Abstract: In this article we investigate multiple testing and variable selection using Least Angle Regression (LARS) algorithm in high dimensions under the Gaussian noise assumption. LARS is known to produce a piecewise affine solutions path with change points referred to as *knots of the LARS path*. The cornerstone of the present work is the expression in closed form of the exact joint law of K-uplets of knots conditional on the variables selected by LARS, namely the so-called *post-selection* joint law of the LARS knots. Numerical experiments demonstrate the perfect fit of our finding.

Our main contributions are three fold. First, we build testing procedures on variables entering the model along the LARS path in the general design case when the noise level can be unknown. This testing procedures are referred to as the Generalized t-Spacing tests (GtSt) and we prove that they have exact non-asymptotic level (i.e., Type I error is exactly controlled). In that way, we extend a work from Tibshirani et al. (2016) where the Spacing test works for consecutive knots and known variance. Second, we introduce a new exact multiple false negatives test after model selection in the general design case when the noise level can be unknown. We prove that this testing procedure has exact non-asymptotic level for general design and unknown noise level. Last, we give an exact control of the false discovery rate (FDR) under orthogonal design assumption. Monte-Carlo simulations and a real data experiment are provided to illustrate our results in this case. Of independent interest, we introduce an equivalent formulation of LARS algorithm based on a recursive function.

Keywords and phrases: Multiple Testing, False Discovery Rate, High-Dimension, Selective Inference.

1. Introduction

Parsimonious models have become ubiquitous tools to tackle high-dimensional representations with a small budget of observations. Successful applications may be found in *Signal Processing* (see for instance the pioneering works of Chen et al. (1998); Candès et al. (2006) and references therein), *Biology* (see for instance Barber et al. (2015) or (Bühlmann and van de Geer, 2011, Chapter 1.4) and references therein). These applications have shown that there exists interesting *almost sparse*

representations in some well chosen basis. Nowadays, in many practical situations, this sparsity assumption is recognized as reasonable.

These important successes have put focus on *High-Dimensional Statistics* and *Compressed Sensing* in the past decades and that may be due to the deployment of tractable algorithms with strong theoretical guarantees. Among the large panoply of methods, one may consider ℓ_1-regularization which benefit from remarkable tractability, empirical performances and theoretical guarantees. Nowadays, sparse regression techniques based on ℓ_1-regularization are a common and powerful tool in high-dimensional settings. Popular estimators, among which one may point LASSO (Tibshirani, 1996) or SLOPE (Bogdan et al., 2015), are known to achieve minimax rate of prediction and to satisfy *sharp oracle inequalities* under conditions on the design such as Restricted Eigenvalue (Bickel et al., 2009; Bellec et al., 2018) or Compatibility (Bühlmann and van de Geer, 2011; van de Geer, 2016). The sharp oracle inequalities show that the estimation errors, in ℓ_1 and ℓ_2 norm, of these estimators are optimal, see for instance (van de Geer, 2016, Chapter 2.7).

Variable selection has been investigating also and it has been proven, see for instance (Bühlmann and van de Geer, 2011, Theorem 7.5), that the LASSO selects the true variables (*i.e.,* there is no false negatives) under *Compatibility condition* and the so-called *beta-min condition* (that assumes that the true parameters are large enough with respect to some threshold that scales linearly with the regularization parameter λ of LASSO). Under a stronger assumption, referred to as the *Irrepresentable condition*, one can prove, see for instance (Bühlmann and van de Geer, 2011, Theorem 7.1), that the ℓ_∞-estimation error scales linearly with the regularization parameter λ of LASSO. As the regularization parameter λ tends to zero, when the number of observation goes to infinity and under some noise assumption, these results show that LASSO produces a consistent selection of the variables (it asymptotically finds the true support with no errors).

Recent advances have focused on a deeper understanding of these techniques looking at selective inference in high dimensions through the prism of confidence intervals on the parameters, testing procedures on the parameters (see (van de Geer, 2016, Chapter 6) and references therein), and false discovery rate control, *e.g.,* Barber et al. (2015) for instance. These new results aim at describing the (asymptotic or non-asymptotic) law of the outcomes of ℓ_1-minimization regression. This line of works adresses important issues encountered in practice. Assessing the uncertainty of popular estimators give strong guarantees on the estimate produced, *e.g.,* the false discovery rate is controlled or a confidence interval on linear statistics of the estimator can be given.

False discovery rate (FDR) control (resp. Confidence intervals (CI)) built upon Debiased LASSO procedure have been studied in Javanmard et al. (2019) (resp. Javanmard and Montanari (2014)) which provides FDR with asymptotic control (resp. CI with asymptotic control of confidence level) for designs with some independent sub-Gaussian rows. FDR control for SLOPE with Benjamini-Hochberg (BH) selection procedure has been proved in Bogdan et al. (2015) for orthogonal designs. Inference after model selection has been studied in several papers, as Fithian et al. (2014); Taylor and Tibshirani (2015) (resp. Tian et al. (2018)) for *selective inference* (resp. a joint estimate of the noise level). The present paper continues these lines

of works and studies the joint law of the knots of the LARS procedure conditional on the support selected by LARS; introduces new testing procedures on variables entering the model along the LARS path (referred to as Generalized t-Spacing test (GtSt)) and on false negatives after model selection, and controls the FDR for a new multiple testing procedure based on GtSt and the BH multiple rejection method (Benjamini and Hochberg, 1995).

1.1. A new formulation of Least Angle Regression algorithm

The Least Angle Regression (LARS) algorithm has been introduced in the seminal article Efron et al. (2004). In the context of linear regression in high dimensions, the LARS algorithm can be used to identify a subset of potential covariates. The LARS outputs a piecewise affine solutions path, and the *knots* $\lambda_1 \geq \lambda_2 \geq \cdots > 0$ are the change points of the LARS path that are built by tracking the ℓ_∞ of the residual. At each knot, the LAR algorithm adds to the active set of variables the covariate the most correlated with the actual residual. In that way, the descent direction is always equiangular to all variables present in the current active set. . This sequence of knots is closely related to the sequence of knots of LASSO (Tibshirani, 1996), as they differ by only one rule: "*Only in the LASSO case, if a nonzero coefficient crosses zero before the next variable enters, drop it from the active set and recompute the current joint least-squares direction*", as mentioned in (Tibshirani et al., 2015, Page 120) or (Efron et al., 2004, Theorem 1) for instance.

In this article, we consider the Least Angle Regression (LARS) algorithm where we denote by $(\lambda_k)_{k \geq 1}$ the sequence of knots and by $(\bar{\iota}_k, \varepsilon_k)_{k \geq 1}$ the sequence of variables $\bar{\iota}_k \in [p]$ and signs $\varepsilon_k \in \{\pm 1\}$ that enter the model along the LARS path. We encode by

$$\widehat{\iota}_k := \bar{\iota}_k + p \left(\frac{1 - \varepsilon_k}{2} \right) \in [2p],$$

both variables $\bar{\iota}_k \in [p]$ and signs $\varepsilon_k \in \{\pm 1\}$, we called them the "signed variables[1]". We recall this algorithm in Algorithm 3 and we present equivalent formulations in Algorithm 4 (using orthogonal projections) and Algorithm 1 (using a recursion). In particular, Algorithm 1 consists in three lines, applying the same function recursively. As far as we know, **Algorithm 1 is new**.

Theorem 1. *Let n, p be integers. Given a vector $Y \in \mathbb{R}^n$ and matrix $X \in \mathbb{R}^{n \times p}$ of rank r then Algorithm 3 (LARS standard formulation), Algorithm 4 (LARS projected formulation) and Algorithm 1 (LARS recursive formulation) output the same sequence $((\lambda_k, \bar{\iota}_k, \varepsilon_k))_{k=1}^r$ from the input given by $\overline{Z} = X^\top Y$ and $\overline{R} = X^\top X$, where $\lambda_1 \geq \lambda_2 \geq \lambda_2 \ldots \geq 0$ are the knots, and $\bar{\iota}_1, \bar{\iota}_2, \ldots, \bar{\iota}_r$ are the variables that enter the model with signs $\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_r$ ($\varepsilon_k = \pm 1$).*

The formulation of Algorithm 3 (LARS standard formulation), Algorithm 4 (LARS projected formulation) and the proof of Theorem 1 are given in Appendices A and B.

---

[1]See Section 2.1 for further details on this notation.

Algorithm 1: LARS algorithm ("recursive" formulation)

```
/* Given a response Y and a design X, set Z̄ = XᵀY and R̄ = XᵀX      */
```
Data: Correlations vector $\overline{Z}$ and variance-covariance matrix $\overline{R}$.

Result: Sequence $((\lambda_k, \bar{\imath}_k, \varepsilon_k))_{k \geq 1}$ where $\lambda_1 \geq \lambda_2 \geq \ldots > 0$ are the knots, and $\bar{\imath}_1, \bar{\imath}_2, \ldots$ are the variables that enter the model with signs $\varepsilon_1, \varepsilon_2, \ldots$ ($\varepsilon_k = \pm 1$).

```
/* Define the recursive function Rec() that would be applied repeatedly.
   The inputs of Rec() are Z a vector, R a SDP matrix and T a vector.   */
```
Function Rec(R, Z, T):

    Compute

$$\lambda = \max_{\{j : T_j < 1\}} \left\{ \frac{Z_j}{1 - T_j} \right\}, \qquad \mathbf{i} = \arg\max_{\{j : T_j < 1\}} \left\{ \frac{Z_j}{1 - T_j} \right\}, \qquad \mathbf{x} = \frac{R_{\mathbf{i}}}{R_{\mathbf{ii}}}.$$

    Update

$$R \leftarrow R - \mathbf{x} R_{\mathbf{i}}^\top, \qquad Z \leftarrow Z - \mathbf{x} Z_{\mathbf{i}}, \qquad T \leftarrow T + \mathbf{x}(1 - T_{\mathbf{i}}).$$

    return (R, Z, T, λ, $\mathbf{i}$)

1 Set $k = 0$, $T = 0$, $Z = (\overline{Z}, -\overline{Z})$ and $R = \begin{bmatrix} \overline{R} & -\overline{R} \\ -\overline{R} & \overline{R} \end{bmatrix}$.

2 Update $k \leftarrow k + 1$ and compute

$$(R, Z, T, \lambda_k, \widehat{\imath}_k) = \text{Rec}(R, Z, T)$$

    Set $\bar{\imath}_k = \widehat{\imath}_k \mod p$ and $\varepsilon_k = 1 - 2(\widehat{\imath}_k - \bar{\imath}_k)/p \in \pm 1$.

1.2. Joint law of LARS knots in Post-Selection Inference

In this paper, we consider the linear model in high-dimensions where the number of observations n may be less than the number of predictors p. We denote by $Y \in \mathbb{R}^n$ the response variable and we assume that

$$Y = X\beta^0 + \eta \sim \mathcal{N}_n(X\beta^0, \sigma^2 \mathrm{Id}_n), \tag{1.1}$$

where $\eta \sim \mathcal{N}_n(0, \sigma^2 \mathrm{Id}_n)$ is some Gaussian noise, the noise level $\sigma > 0$ may be known or that has to be estimated depending on the context, and $X \in \mathbb{R}^{n \times p}$ has rank $r > 0$.

For a short moment, consider the simplest linear model where one observes the target vector $\beta^0 = (\beta_1^0, \ldots, \beta_p^0) \in \mathbb{R}^p$, namely there is no noise and the design $X = \mathrm{Id}_p$ is the identity. In this case, LASSO and LARS give the same knots $\lambda_1, \lambda_2, \ldots$ and LASSO reduces the proximal operator of the ℓ_1-norm at point $\beta^0 \in \mathbb{R}^p$, see for instance (Tibshirani et al., 2015, Chapter 2). In this simple case, we deduce that the knots are

$$\lambda_k = \beta_{(k)}^0, \tag{1.2}$$

where we have considered the reordering $\beta_{(1)}^0 \geq \beta_{(2)}^0 \geq \ldots$ on the entries of the target. Obviously, this fact is no longer true for general designs in high-dimensions with noise but one may ask:

[Q1] *What is the **joint law** of the LARS knots $\lambda_1, \lambda_2, \dots$ and how do they relate to the target β^0?*

We will answer [**Q1**] in high-dimensions under Gaussian noise assumption in Section 3.1.3 and Section 3.2. Working with the so-called "*Irrepresentable Check*" Condition[2] ($\mathscr{A}_{\mathrm{Irr.}}$), which can be efficiently checked in practice, we are able to provide the joint law of the LAR's knots conditionally on the so-called "selection event" defined by

$$\mathscr{E} := \left\{ \widehat{\iota}_1 = \iota_1, \dots, \widehat{\iota}_K = \iota_K, \lambda_{K+1} \right\}.$$

This selection event states that the signed variable ι_k has been selected by LARS algorithm at its k-th step for $k = 1, \dots, K$. This is the cornerstone of the paper, showing that **the conditional joint distribution of the LARS knots is a mixture of Gaussian order statistics as presented in the next theorem**.

Theorem 2 (Conditional Joint Law of the LARS knots)**.** *Let $(\lambda_1, \dots, \lambda_K, \lambda_{K+1})$ be the first knots of the LARS and let $(\widehat{\iota}_1, \dots, \widehat{\iota}_K, \widehat{\iota}_{K+1})$ be the first variables entering along the LARS path. If $(\widehat{\iota}_1, \dots, \widehat{\iota}_K)$ satisfies ($\mathscr{A}_{\mathrm{Irr.}}$) then, conditional on $\{\widehat{\iota}_1, \dots, \widehat{\iota}_K, \lambda_{K+1}\}$, the vector $(\lambda_1, \dots, \lambda_K)$ has law with density (w.r.t. the Lebesgue measure)*

$$Q^{-1}_{(\widehat{\iota}_1, \dots, \widehat{\iota}_K, \lambda_{K+1})} \Big(\prod_{k=1}^{K} \varphi_{m_k, v_k^2}(\ell_k) \Big) \mathbb{1}_{\{\ell_1 \geq \ell_2 \geq \cdots \geq \ell_K \geq \lambda_{K+1}\}} \ \textit{at point } (\ell_1, \ell_2, \dots, \ell_K),$$

where $Q_{(\widehat{\iota}_1, \dots, \widehat{\iota}_K, \lambda_{K+1})}$ is a normalizing constant, φ_{m_k, v_k^2} is the standard Gaussian density with mean m_k and variance $v_k^2 := \sigma^2 \rho_k^2$ are explicitly given by (3.12) and (3.13).

The proof of this theorem is given in Section 3.2.1. Now, let us describe the dependency between (m_k, ρ_k^2) and $\overline{\mu}^0 := X^\top X \beta^0$. For a design matrix X with columns $(X_j)_{j=1}^p$, we denote[3]

$$\{0\} =: H_0 \subset H_1 \subset \cdots \subset H_k := \mathrm{Span}(X_{\overline{\iota}_1}, \dots, X_{\overline{\iota}_k}) \subset \cdots \subset H_K.$$

By (3.12) and (3.13), one has

$$\forall k \in [K], \quad m_k = c_k\, \varepsilon_k\, \langle X_{\overline{\iota}_k}, P_{k-1}^\perp(X\beta^0) \rangle \quad \text{and} \quad \rho_k^2 = d_k\, \sin \measuredangle(X_{\overline{\iota}_k}, H_{k-1}),$$

where $c_k, d_k > 0$ are constants that depends only on $X_{\overline{\iota}_1}, \dots, X_{\overline{\iota}_{k-1}}$, $P_{k-1}^\perp$ denotes the orthogonal projection onto the orthogonal of H_{k-1}, ε_k is the sign of the k-th variable entering the LARS path, and $\measuredangle(X_{\overline{\iota}_k}, H_{k-1})$ is the angle between $X_{\overline{\iota}_k}$ and H_{k-1}.

1.3. The Generalized t-Spacing test (GtSt)

This paper introduces a class of exact tests built from ℓ_1-minimization regression in high-dimensions. More precisely, we design a testing procedure for a null hypothesis of the form

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_{a_0} \text{''},$$

---

[2]See Section 2.3 for a definition and detailed comments on this assumption.

[3]Recall that the selected variable $\widehat{\iota}_k \in [2p]$ are decomposed into $\widehat{\iota}_k := \overline{\iota}_k + p\left(\frac{1-\varepsilon_k}{2}\right)$.

where $H_{a_0} := \mathrm{Span}(X_{\bar{\imath}_1}, \dots, X_{\bar{\imath}_{a_0}})$. Note that the null $\mathbb{H}_0$ is equivalent to the hypothesis that all the true positives (i.e., the support of β^0) are among the first a_0 variables selected by LARS, namely $\{\bar{\imath}_1, \dots, \bar{\imath}_{a_0}\}$. Following the original idea of Lockhart et al. (2014), we study testing procedures of $\mathbb{H}_0$ based on the knots of the LARS path. Remark that, conditional on the selection event, the law of three **consecutive** knots has been studied by Lockhart et al. (2014) referred to as the *Spacing test* (ST) (Tibshirani et al., 2015). The article Azaïs et al. (2018) proved that *Spacing test* is unbiased and introduce a *studentized* version of this test. In the same direction, inference after model selection has been studied in several papers, as Fithian et al. (2014); Taylor and Tibshirani (2015) and respectively Tian et al. (2018) for *selective inference* and respectively a joint estimate of the noise level. It raises the following questions.

[Q2] *Can we provide exact testing procedures based on knots that are* **not** *consecutive?*

[Q3] *What is the most powerful test among these Spacing tests?*

[Q4] *Can we provide* **exact** *testing procedures when the noise level is not known, and how do we estimate the noise level without bias in this case?*

In regard of these latter questions, our contribution is three-fold:

i) First, our test is based on the conditional joint law of three, **not necessarily consecutive**, knots $a_0 \le a < b < c \le K + 1$. In that way, we extend the work from Tibshirani et al. (2016) where the Spacing test works for consecutive knots. We present this framework in Section 3.2 and we referred to these new tests are *Generalized Spacing Tests* (GSt). At the first reading of the next theorem, one can set $\widehat{m} = a_0$ for a fixed value $0 \le a_0 \le a$. The selection procedure will be presented in Section 2.5 and Section 4.1, with the notion of "admissible procedure" ($\mathscr{A}_{\mathrm{Stop}}$).

Theorem 3. *Let a, b, c be such that $0 \le a < b < c \le K + 1$. Let $(\lambda_1, \dots, \lambda_K, \lambda_{K+1})$ be the first knots and let $(\widehat{\imath}_1, \dots, \widehat{\imath}_K)$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \dots, \widehat{\imath}_K)$ satisfies ($\mathscr{A}_{\mathrm{Irr.}}$) and $\widehat{m}$ is chosen according to a procedure satisfying ($\mathscr{A}_{\mathrm{Stop}}$) then under the null hypothesis*

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_a \text{''},$$

and conditional on the selection event $\{\widehat{m} \le a\}$ it holds that

$$\widehat{\alpha}_{abc} = \widehat{\alpha}_{abc}(\lambda_a, \lambda_b, \lambda_c, \widehat{\imath}_{a+1}, \dots, \widehat{\imath}_{c-1}) := 1 - \frac{\mathbb{F}_{abc}(\lambda_b)}{\mathbb{F}_{abc}(\lambda_a)} \sim \mathscr{U}(0, 1), \qquad (1.3)$$

namely, it is uniformly distributed over $(0, 1)$.

The proof of Theorem 3 is presented in Section 3.2.3. The construction of the p-values $\widehat{\alpha}_{abc}$ and of $\mathbb{F}_{abc}$ is given in (3.19) and Section 3.2.2 respectively. We consider the following Generalized Spacing test procedures (GSt)

$$\mathscr{S}_{abc} := \mathbb{1}_{\{\widehat{\alpha}_{abc} \le \alpha\}}, \qquad (1.4)$$

that rejects if the p-value $\widehat{\alpha}_{abc}$ is less than the level α of the test.

One may remark that

> **the p-value $\widehat{\alpha}_{abc}$ detects abnormally large values of λ_b relatively to the interval (λ_a, λ_c).**

When **the noise variance is unknown**, we introduce the *Generalized t-Spacing Tests* (GtSt) whose theoretical guarantees are given be the next theorem.

Theorem 4. *Let a, b, c be such that $0 \leq a < b < c \leq K + 1$. Let $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ be the first knots and let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \widehat{\imath}_{K+1})$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$ and $\widehat{m}$ is chosen according to a procedure satisfying $(\mathscr{A}_{\mathrm{Stop}})$ then under the null hypothesis*

$$\mathbb{H}_0 \,:\, \text{``}X\beta^0 \in H_a\text{''},$$

and conditional on the selection event $\{\widehat{m} \leq a\}$ it holds that

$$\widehat{\beta}_{abc} = \widehat{\beta}_{abc}(\lambda_a, \lambda_b, \lambda_c, \widehat{\imath}_1, \ldots, \widehat{\imath}_{K+1}, \widehat{\sigma}_{\mathrm{test}}) := 1 - \frac{\widetilde{\mathbb{F}}_{abc}(\Lambda_b)}{\widetilde{\mathbb{F}}_{abc}(\Lambda_a)} \sim \mathscr{U}(0, 1),$$

namely, it is uniformly distributed over $(0, 1)$.

The proof of Theorem 4 is presented in Section 3.4.1. The construction of the p-values $\widehat{\beta}_{abc}$, of $\widetilde{\mathbb{F}}_{abc}$ and of the estimation of the noise $\widehat{\sigma}_{\mathrm{test}}$ is given in (3.24), Section 3.23 and Section 2.4 respectively. One may remark that

> **the p-value $\widehat{\beta}_{abc}$ detects abnormally large values of $\lambda_b/\widehat{\sigma}_{\mathrm{test}}$ relatively to the interval $(\lambda_a/\widehat{\sigma}_{\mathrm{test}}, \lambda_c/\widehat{\sigma}_{\mathrm{test}})$.**

ii) Working with three consecutive knots, we recover the Spacing test of Tibshirani et al. (2016) and even in this framework, this paper improves the current state of knowledge. We prove that:

○ *Under $(\mathscr{A}_{\mathrm{Irr.}})$, the Spacing test procedure defined in (Tibshirani et al., 2016, Theorem 1) is exact, and is equal to the so-called "conservative" Spacing test defined in (Tibshirani et al., 2016, Theorem 2).*

The exact formulation of the Spacing test of the pioneer work Tibshirani et al. (2016) requires extra-computations of the term denoted by M^+ in (Tibshirani et al., 2016, Lemma 5). They proved that the Spacing test is asymptotically equivalent to the conservative Spacing test. We remove this restriction and we prove that it suffices to check wether Irrepresentable Check Condition $(\mathscr{A}_{\mathrm{Irr.}})$ holds to get a non-asymptotic equivalence between the Spacing test and the conservative Spacing test.

iii) We theoretically prove that working with non-consecutive knots can allow to reach higher power for the testing procedure.

Algorithm 2: Exact false negative testing after model selection
---
Data: K satisfying (2.9), selection procedure $\widehat{m}$ satisfying ($\mathscr{A}_{\text{Stop}}$), couple (X, Y) giving design and response.

Result: p-value $\widehat{\alpha}$ on the existence of false negative.

/* $\mathbb{1}_{\{\widehat{\alpha} \leq \alpha\}}$ is a testing procedure with level exactly α */

1 Compute the LARS path from (X, Y).

2 Check that $(\widehat{\iota}_1, \ldots, \widehat{\iota}_K)$ satisfies ($\mathscr{A}_{\text{Irr}}$). If not **Stop**.

3 Compute $\widehat{m}$, the size of the selected model.

4 **Return** $\widehat{\alpha} = \widehat{\alpha}_{\widehat{m}(\widehat{m}+1)(K+1)}$, see (1.3).

/* When variance is unknown, $\widehat{\alpha} = \widehat{\beta}_{\widehat{m}(\widehat{m}+1)(K+1)}$, see (3.24).   */

Theorem 5. *Assume that the design X is orthogonal, namely $X^\top X = \text{Id}_p$. Let a_0 be an integer such that $0 \leq a_0 \leq K - 1$. If $\widehat{m}$ is chosen according to a procedure satisfying ($\mathscr{A}_{\text{Stop}}$) then under the null hypothesis*

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_{a_0} \text{''},$$

and conditional on the selection event $\{\widehat{m} = a_0\}$, it holds the test $\mathscr{S}_{a_0, a_0+1, K+1}$ is uniformly most powerful than any of the tests $\mathscr{S}_{a,b,c}$ for $a_0 \leq a < b < c \leq K + 1$.

The proof of this result is given in Appendix C.4. It shows that the most powerful test among the set of tests $(\mathscr{S}_{a,b,c})_{a_0 \leq a < b < c \leq K+1}$ is given by

the GSt test $\mathscr{S}_{a_0, a_0+1, K+1}$ with the smallest a and the largest c.

More precisely, in the proof of Theorem 5, it is shown that

$$\widehat{\alpha}_{ab(c+1)} \preccurlyeq \widehat{\alpha}_{abc} \text{ and } \widehat{\alpha}_{a(b-1)c} \preccurlyeq \widehat{\alpha}_{abc} \text{ and } \widehat{\alpha}_{(a-1)bc} \preccurlyeq \widehat{\alpha}_{abc},$$

for orthogonal designs, where $\preccurlyeq$ denotes stochastic ordering.

1.4. A new exact testing procedure on False Negatives (FN) after support selection

One specific task is to estimate the support of the target sparse vector, namely identify *true positives* in a context of multiple testing procedure. In particular, one may take the support of LASSO (or SLOPE) solution as an estimate of the support of the solution. This strategy has been intensively studied in the literature, one may consider Wainwright (2009); Bogdan et al. (2015); van de Geer (2016); Bellec et al. (2018) and references therein. Support selection has been studied under the so-called "*Irrepresentable Condition*" (IC), as presented for instance in the books (van de Geer, 2016, Page 53) and (Bühlmann and van de Geer, 2011, Sec. 7.5.1) and also referred to as the "*Mutual Incoherence Condition*" (Wainwright, 2009). Under the so-called "*Beta-Min Condition*", one may prove (Bühlmann and van de Geer, 2011; van de Geer, 2016) that the LASSO asymptotically returns the true support. Following this line of works, one may ask:

[Q5] *Can we provide a false negative testing procedure, after model selection, with a controlled Type I error?*

In this article, we build an exact non-asymptotic multiple test on false non-negatives, see Sections 3.3 and 3.4. The control of the false negatives after model selection in the unknown noise level case is given in Section 3.4 and the procedure is introduced in Algorithm 2. We assume ($\mathscr{A}_{\text{Stop}}$) that considers that the model has been selected using an "admissible" procedure which essentially means that the decision to select a model of size a only depends on the orthogonal projection of the observation Y onto $H_a = \text{Span}(X_{\bar{\imath}_1}, \ldots, X_{\bar{\imath}_a})$. Assuming further that ($\mathscr{A}_{\text{Irr.}}$) holds, we provide an exact testing method on false negatives. In order to reach high power, the test statistic is the p-value of three non-consecutive knots of the LARS path. To compute this p-value, one needs to marginalize the joint law of the knots, leading to a numerical integration whose complexity grows exponentially with the space between the indices of the knots. We propose to use QMC techniques to compute the statistic, see Appendix D.

1.5. False Discovery Rate control for LARS

Simultaneous controls of confidence intervals independently of the selection procedure have been studied under the concept of *post-selection constants* as introduced in Berk et al. (2013) and studied for instance in Bachoc et al. (2018). Asymptotic confidence intervals can be build using the *de-sparsified LASSO*, the reader may refer to (van de Geer, 2016, Chapter 5) and references therein. We also point a recent study (Javanmard et al., 2019) of the FDR control as the sample size tends to infinity using *de-biased LASSO*, which has been implemented in Section 4.3. Asymptotic FDR control has been studied in Barber et al. (2015) and references therein, which has been implemented in Section 4.3. Let us point recent control of the *Joint family-wise Error Rate* as in Blanchard et al. (2017) and references therein. Following these lines of work, one may ask:

[Q6] *Can we provide multiple Spacing Tests with a controlled False Discovery Rate (FDR)?*

To the best of our knowledge, this paper is the first to study the joint law and an exact control of multiple spacing tests of LARS knots in a non-asymptotic frame, see Sections 3.2 and 3.6. We investigate the consecutive *spacings* of knots of the LARS as testing statistics and we prove an exact FDR control using a Benjamini–Hochberg procedure (Benjamini and Hochberg, 1995) in the orthogonal design case, see Theorem 16 and Section 3.6. Our proof (see Appendix C.7) is based on the *Weak Positive Regression Dependency* (WPRDS), the reader may consult Blanchard et al. (2008) or the survey Roquain (2011), and *Knothe-Rosemblatt transport*, see for instance (Santambrogio, 2015, Sec.2.3, Page 67) or (Villani, 2008, Page 20), which is based on conditional quantile transforms.

1.6. Outline of the paper

1.6.1. Dependency diagram

The outline can be depicted by the following *dependency diagram*:

| Assumptions & tools | | Results |
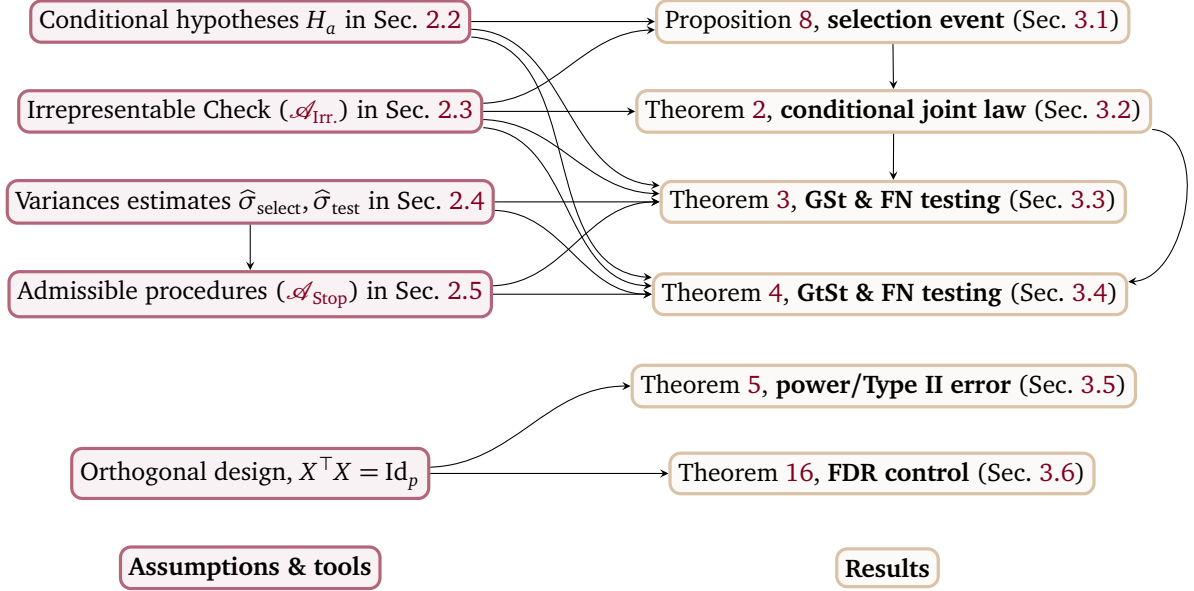

1.6.2. Detailed outline

Section 2 introduces notation (see also Table 1 next page), assumptions ($\mathscr{A}_{\text{Irr.}}$) and ($\mathscr{A}_{\text{Stop}}$), and variance estimates $\widehat{\sigma}_{\text{select}}$ and $\widehat{\sigma}_{\text{test}}$. The variance estimates are a key step in our testing procedures: we introduce new variance estimates with useful property to derive exact and non-asymptotic post-selection laws, see Section 2.4.

The main assumption is based on the condition of *"Irrepresentable Check"* ($\mathscr{A}_{\text{Irr.}}$) that can be checked in practice, see Section 2.3. Under ($\mathscr{A}_{\text{Irr.}}$), we show a new characterization of the it selection event in Proposition 8 of Section 3.1.

Section 3 gives the main results: Section 3.2 describes the joint distribution of the LARS knots as a *mixture of Gaussian order statistics* and the GST and GtST tests. The power in the orthogonal case is considered in Section 3.5. Control of false negative in a post selection inference with estimation of the variance is presented in Section 3.4 (when the variance is known this procedure is studied in Section 3.3). A procedure of control of the false discovery rate in the orthogonal case is presented in Section 3.6.

An illustration of our method, both on simulated data and on real data, is presented in Section 4. A Zenodo repository of the code used in all our experiments can be found at De Castro (2021).

Notation	Comment
	General notation
$[a]$	the set of integers $\{1,\dots,a\}$
$Y = X\beta^0 + \eta$	Linear Model (1.1), X is $n \times p$ design matrix with rank r
σ^2	the variance of the errors η
K	the number of knots $\lambda_1,\dots,\lambda_K$ that are considered, see (2.9)
n_1, n_2	number of d.o.f. used for constructing $\widehat{\sigma}_{\text{select}}, \widehat{\sigma}_{\text{test}}$
φ_{m_k, v_k^2}	standard Gaussian density with mean m_k and variance $v_k^2 := \sigma^2 \rho_k^2$
$\widetilde{\varphi}$	multivariate t-distribution with $v = n_2$ degrees of freedom, mean $m = (m_1,\dots,m_K)$ and variance-covariance matrix $\text{Diag}(\rho_1,\dots,\rho_K)$
m_k, v_k^2	conditional mean, see (3.12), and conditional variance $v_k^2 = \sigma^2 \rho_k^2$, see (3.13)
$\widehat{a}_{abc}$	the p-value of the *generalized spacing test* (GSt), see (1.3)
$\mathscr{S}_{abc}$	$\mathbb{1}_{\{\widehat{a}_{abc} \le \alpha\}}$, the *generalized spacing test* (GSt) see (1.4)
Λ_k	t-knots defined by (3.22)
$\widehat{\beta}_{abc}$	the p-value of the *generalized t-spacing test* (GtSt), see (3.24)
$\mathscr{T}_{abc}$	$\mathbb{1}_{\{\widehat{\beta}_{abc} \le \alpha\}}$, the *generalized t-spacing test* (GtSt), see (3.26)
	Technical notation
$\widehat{i}_k$	a way of coding both indexes and signs, see (2.1)
$\overline{i}_k; \varepsilon_k$	the indexes and the signs of the variables that enter in the LARS path
$j_1,\dots,j_k; s_1,\dots,s_k$	a generic value of the sequences above
$i_1,\dots,i_k$	a generic value of the sequence $\widehat{i}_k$
Z	the vector of correlations, obtained by symmetry from $\overline{Z}$ defined by (2.2)
R	the variance-covariance matrix of Z, see (2.4)
$M_{i_1,\dots,i_\ell}$	sub-matrix of R indexed by $\{i_1,\dots,i_\ell\}$, see (2.11)
$\overline{S}^k$	$\{\overline{i}_1,\dots,\overline{i}_k\}$, a possible selected support (2.6)
S_0	the true support
$\widehat{S}$	the chosen set of variables : $\overline{S}^{\widehat{m}}$, see (2.7)
$\widehat{m}$	the chosen size
$(\mathscr{A}_{\text{Stop}})$	stopping rule, see Section 2.5
H_k	$\text{Span}(X_{\overline{i}_1},\dots,X_{\overline{i}_k})$
$P_k(P_k^\perp)$	Orthogonal projector on (the orthogonal of) H_k
$(\mathscr{A}_{\text{Irr}})$	Irrepresentable Check, see $(\mathscr{A}_{\text{Irr}})$
$\theta_j(i_1,\dots,i_k)$	expectation of Z_j conditional on $Z_{i_1} = \cdots = Z_{i_k} = 1$, see (2.10), and $\theta^\ell := \theta(\widehat{i}_1,\dots,\widehat{i}_\ell)$
$Z_j^{(i_1,\dots,i_k)}$	frozen residual, see (3.1)
$\Pi_{i_1,\dots,i_k}(Z_j)$	regression of Z_j on $(Z_{i_1},\dots,Z_{i_k})$, see (3.2)
$\lambda_k^f := Z_{\overline{i}_k}^{i_1,\dots i_{k-1}}$	the k-th frozen knot, see (3.5)
$m_k^f, \sigma \rho_k^f$	mean (3.7) and standard deviation (3.8) of λ_k^f
$\mathbb{F}_{abc}(t)$	up to some numerical constant, the CDF of $\lambda_b \mid \lambda_a, \lambda_c$, see (3.19)
$F_i; \mathscr{P}_{ij}$	$F_i := \Phi_i(\lambda_i) := \Phi(\lambda_i/(\sigma \rho_i))$ and $\mathscr{P}_{ij}$ is given by (3.16)
$\widetilde{\mathbb{F}}_{abc}(t)$	up to some numerical constant, the CDF of $\Lambda_b \mid \Lambda_a, \Lambda_c$, see (3.23)
T_k	up to some numerical constant, the CDF of centered t-Student distribution, see (3.27)

TABLE 1

Table of notations (and commands).

2. Assumptions, Variance Estimations and Admissible Procedures

2.1. Signed variables of LARS

We give some notation that will be useful. We denote by $(\widehat{\iota}_1,\ldots,\widehat{\iota}_k) \in [2p]^k$ the *"signed"* variables that enter the model along the LARS path with the convention that

$$\widehat{\iota}_k := \overline{\iota}_k + p\left(\frac{1-\varepsilon_k}{2}\right), \tag{2.1}$$

so that $\widehat{\iota}_k \in [2p]$ is a useful way of encoding both the variable $\overline{\iota}_k \in [p]$ and its sign $\varepsilon_k = \pm 1$ as used in Algorithm 1. We denote by $\overline{Z} := X^\top Y$ the *correlation* vector such that $\overline{Z}_k$ is the scalar product between the k-th predictor and the response variable, and we denote by $\sigma^2 \overline{R}$ its *variance-covariance* matrix. For sake of presentation, we may consider the $2p$-vector

$$Z := (\overline{Z}, -\overline{Z}) = (X^\top Y, -X^\top Y), \tag{2.2}$$

whose mean is given by

$$\mu^0 := (\overline{R}\beta^0, -\overline{R}\beta^0) = (X^\top X \beta^0, -X^\top X \beta^0) = (\overline{\mu}^0, -\overline{\mu}^0), \tag{2.3}$$

and whose variance-covariance matrix is $\sigma^2 R$ with

$$R = \begin{bmatrix} \overline{R} & -\overline{R} \\ -\overline{R} & \overline{R} \end{bmatrix} = \begin{bmatrix} X^\top X & -X^\top X \\ -X^\top X & X^\top X \end{bmatrix}. \tag{2.4}$$

We also denote by

- $\widehat{\iota}_1,\ldots,\widehat{\iota}_k$, the first k signed variables entering the LARS,
- $i_1,\ldots,i_k$, a generic value of the sequence above,

- $\overline{\iota}_1,\ldots,\overline{\iota}_k$, the first k variables entering the LARS,
- $j_1,\ldots,j_k$, a generic value of the sequence above,

- $\varepsilon_1,\ldots,\varepsilon_k$, the first k signs of the coefficients of the variables entering in the LARS,
- $s_1,\ldots,s_k$, a generic value of the sequence above.

The quantities above are related by (2.1) and

$$i_k := j_k + p\left(\frac{1-s_k}{2}\right). \tag{2.5}$$

2.2. Models, conditional hypotheses, and the notation K

We are interested in selecting the true support S^0 of β^0, where the support is defined by

$$S^0 := \left\{ k \in [p] \; : \; \beta_k^0 \neq 0 \right\}.$$

To estimate this support, we will consider the models that appear along the LARS path: the selected model $\widehat{S}$ would be chosen among the family of nested models

$$\underbrace{\{\bar{\imath}_1\}}_{\bar{S}^1} \subset \underbrace{\{\bar{\imath}_1, \bar{\imath}_2\}}_{\bar{S}^2} \subset \cdots \subset \underbrace{\{\bar{\imath}_1, \bar{\imath}_2, \ldots, \bar{\imath}_a\}}_{\bar{S}^a} \subset \cdots \subset \underbrace{\{\bar{\imath}_1, \bar{\imath}_2, \ldots, \bar{\imath}_K\}}_{\bar{S}^K}, \qquad (2.6)$$

where K denotes the maximal model size. We denote $\widehat{m}$ the size of the selected model $\widehat{S}$ and it holds

$$\widehat{S} = \bar{S}^{\widehat{m}}. \qquad (2.7)$$

Respectively, denote

$$\{0\} =: H_0 \subset H_1 \subset \cdots \subset H_a := \mathrm{Span}(X_{\bar{\imath}_1}, \ldots, X_{\bar{\imath}_a}) \subset \cdots \subset H_K, \qquad (2.8)$$

the corresponding family of nested subspaces of $\mathbb{R}^n$. Once the model has been selected, we will construct tests based on the $K + 1$ first knots of the LARS.

Remark 1. *The testing procedures under consideration are not standard since the $(H_a)_{a=1}^K$ are random subspaces. We are interested in the framework of* selective testing, *namely testing procedures conditional on the selection event $\{\widehat{m} = a, \widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_{K+1} = i_{K+1}\}$, for some fixed $a \in [K-1]$. Conditional on the event, note that H_a is fixed. By convention, we may consider the case $a = 0$, that is testing the* global nul hypothesis.

Throughout this paper, we assume that

$$K \text{ is fixed and such that } 1 \leq K < \min(n-3, r) \text{ where } r = \mathrm{rank}(X). \qquad (2.9)$$

In practice, K can be considerably much smaller than n. Our analysis is conditional on $(\widehat{\imath}_1, \ldots, \widehat{\imath}_{K+1})$ and in this spirit it can be referred to as a "*Post-Section*" procedure, see *e.g.* Taylor and Tibshirani (2015); Tibshirani et al. (2016, 2015).

2.3. Irrepresentable Check on the Active sets

We define the set of *Active Sets* $\mathscr{A}_K$ as all the sequences $i_1, \ldots, i_K$ of signed variables such that $j_1, \ldots, j_K$ are pairwise different, where the j's are defined by (2.5), namely

$$\mathscr{A}_K := \left\{ (i_1, \ldots, i_K) \in [2p]^K \; : \; j_1, \ldots, j_K \text{ are pairwise different} \right\}.$$

Sometimes it would be useful to consider $\mathscr{A}_{K+1}$, the set of active sets of size $K + 1$. We introduce *Irrepresentable Check* which is the only assumption on the design and the selected active set in most of our results.

Definition 1 (Irrepresentable Check)**.** *An active set* $(i_1, \ldots, i_K) \in \mathscr{A}_K$ *said to satisfy the Irrepresentable Check condition if*

$$\forall k \in [K], \ \forall j \notin T^k := \{j_1, \ldots, j_k\}, \quad X_j^\top X_{T^k} \left(X_{T^k}^\top X_{T^k} \right)^{-1} s_k < 1, \qquad (\mathscr{A}_{\mathrm{Irr.}})$$

where j_k and s_k are defined from i_k using (2.5). By a small abuse of notation we will denote by ($\mathscr{A}_{\mathrm{Irr.}}$) the set of sequences $(i_1, \ldots, i_K)$ that satisfy this property.

In our procedures and theoretical results, we will limit our attention to sequences of chosen variables $\widehat{\iota}_1, \ldots, \widehat{\iota}_K$ by LARS that satisfy ($\mathscr{A}_{\mathrm{Irr.}}$). A particular case is when the property is true for all possible active sets. This is equivalent to the *Irrepresentable Condition* that we recall here.

Definition 2 (Irrepresentable Condition of order K)**.** *The design matrix X satisfies the Irrepresentable Condition of order K if and only if*

$$\forall S \subset [p] \ s.t. \ \#S \leq K, \quad \max_{j \in [p] \setminus S} \max_{\|v\|_\infty \leq 1} X_j^\top X_S \left(X_S^\top X_S \right)^{-1} v < 1, \qquad (\mathrm{Irrep.})$$

where X_j denotes the jth column of X and X_S the sub-matrix of X obtained by keeping the columns indexed by S.

Remark 2. *Note that the "Irrepresentable Condition" is a standard condition, as presented for instance, in the books (van de Geer, 2016, Page 53) and (Bühlmann and van de Geer, 2011, Sec. 7.5.1) and also referred to as the "Mutual Incoherence Condition" (Wainwright, 2009).*

Remark 3. *This condition has been intensively studied in the literature and it is now well established that some random matrix models satisfies it with high probability. For instance, one may refer to the article Wainwright (2009) where it is shown that a design matrix $X \in \mathbb{R}^{n \times p}$ whose rows are drawn independently with respect to a centered Gaussian distribution with variance-covariance matrix satisfying (Irrep.) (for instance the Identity matrix) satisfies (Irrep.) with high probability when $n \gtrsim K \log(p - K)$, where $\gtrsim$ denotes an inequality up to some multiplicative constant.*

In practice, the Irrepresentable Condition (Irrep.) is a strong requirement on the design X and, additionally, this condition cannot be checked in polynomial time. One important feature of our results is that we do not require *Irrepresentable Condition* (Irrep.) but the weaker requirement *Irrepresentable Check* ($\mathscr{A}_{\mathrm{Irr.}}$) on the selected active set. Namely, we would assume that

$$\text{For } K \text{ defined by (2.9), } (\widehat{\iota}_1, \ldots, \widehat{\iota}_K) \text{ satifies } (\mathscr{A}_{\mathrm{Irr.}}). \qquad \text{(Assumption)}$$

Given $(\widehat{\iota}_1, \ldots, \widehat{\iota}_K)$, note that this condition can be checked in polynomial time.

Example 4. *Taking the (signed) variables entering the model with LARS on a iid Gaussian design and response variable a centered Gaussian vector with iid entries on $10,000$ Monte-Carlo repetitions, we draw the law of the maximal order $K_{\max}$ for which Irrepresentable Check holds in Figure 1. For example, we found that for $p = 1,000$ and $n = 100$ (with ratio $n/p = 0.1$) resp. $n = 500$ (with ratio $n/p = 0.5$), Irrepresentable Check ($\mathscr{A}_{\mathrm{Irr.}}$) of order $K_{\max}$ holds when $K_{\max}$ is about $K_{\max} \simeq 0.16 \times n = 16$ respectively $K_{\max} \simeq 0.12 \times n = 60$, see Figure 1.*
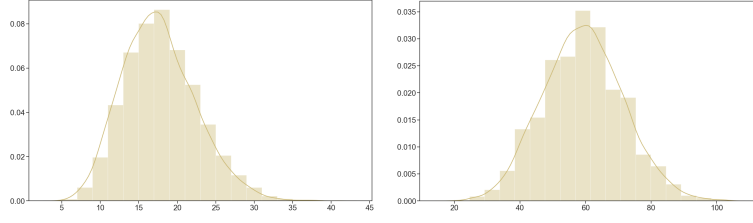

14

Figure 1: Taking the (*signed*) variables entering the model with LARS on a iid Gaussian design and response variable a centered Gaussian vector with iid entries on $10,000$ Monte-Carlo repetitions, we draw the law of the maximal order K for which *Irrepresentable Check* holds. In these experiments, we have $p = 1,000$ predictors and $n = 100$ (left) $n = 500$ (right) observations, and we observe that $K_{\max} \in [10,27]$ (left) and $K_{\max} \in [39,81]$ (right) for 95% of the values.

2.3.1. Irrepresentable Check: an equivalent formulation

Now, we can define

$$\forall (i_1,\dots,i_k) \in [2p]^k, \quad \theta_j(i_1,\dots,i_k) := \left(R_{j,i_1} \cdots R_{j,i_k} \right) M_{i_1,\dots,i_k}^{-1} (1,\dots,1), \qquad (2.10)$$

where $(1,\dots,1)$ is the column vector of size k whose entries are equal to one; $\sigma^2 M_{i_1,\dots,i_k}$ is the variance-covariance matrix of the vector $(Z_{i_1},\cdots,Z_{i_k})$ and $(R_{j,i_1} \cdots R_{j,i_k})$ is a row vector of size k. Note that $M_{i_1,\dots,i_k}$ is the submatrix of R obtained by keeping the columns and the rows indexed by $\{i_1,\dots,i_k\}$, namely

$$M_{i_1,\dots,i_k} := (R_{i,j})_{i,j=i_1,\dots,i_k}. \qquad (2.11)$$

Remark that

$$\theta_j(i_1,\dots,i_k) = \mathbb{E}\left[Z_j \mid Z_{i_1} = 1,\dots,Z_{i_k} = 1 \right],$$

when $\mathbb{E}Z = 0$. Then Proposition 6 shows that the *Irrepresentable Condition* (Irrep.) of order K is equivalently given by

$$\forall k \leq K, \ \forall (i_1,\dots,i_k) \in [2p]^k, \ \forall j \notin \{i_1,\dots,i_k\}, \quad \theta_j(i_1,\dots,i_k) < 1, \qquad (2.12)$$

where $\theta_j(i_1,\dots,i_k)$ is given by (2.10).

Proposition 6. *Let X and R be defined by* (2.4) *then the following assumptions are equivalent:*

- *the design matrix X satisfies* (Irrep.) *of order K,*
- *the variance-covariance matrix R satisfies* (2.12) *of order K.*

Furthermore, they imply that for all $(i_1,\dots,i_K) \in \mathscr{A}_K$ it holds

$$\max\left[\max_{j \neq \hat{\imath}_1} \theta_j(\iota_1), \ \dots, \ \max_{j \neq i_1,\dots,i_K} \theta_j(i_1,\dots,i_K) \right] < 1$$

which is an equivalent formulation of $(i_1,\dots,i_K)$ satisfying $(\mathscr{A}_{\mathrm{Irr.}})$.

15

Proof. Let $S = \{j_1, \ldots, j_k\} \subset [p]$ and $j \in [2p] \setminus S$. Let $\overline{v} = (\overline{v}_1, \ldots, \overline{v}_k) \in \{-1, 1\}^k$ and define $i_\ell = j_\ell + p(1 - \overline{v}_\ell)/2$ for $\ell \in [k]$. Note that

$$
\begin{aligned}
\theta_j(i_1, \ldots, i_k) &= \left(R_{j,i_1} \cdots R_{j,i_k}\right) M_{i_1,\ldots,i_k}^{-1}(1, \ldots, 1) \\
&= \left[X_j^\top X_S \mathrm{Diag}(\overline{v})\right] M_{i_1,\ldots,i_k}^{-1}(1, \ldots, 1) \\
&= \left[X_j^\top X_S \mathrm{Diag}(\overline{v})\right] M_{i_1,\ldots,i_k}^{-1}\left[\mathrm{Diag}(\overline{v})\overline{v}\right] \\
&= X_j^\top X_S \left[\mathrm{Diag}(\overline{v}) M_{i_1,\ldots,i_k}^{-1} \mathrm{Diag}(\overline{v})\right]\overline{v} \\
&= X_j^\top X_S \left(X_S^\top X_S\right)^{-1}\overline{v}.
\end{aligned}
$$

Now, observe that

$$
\max_{\|v\|_\infty \leq 1} v^\top \left(X_S^\top X_S\right)^{-1} X_S^\top X_j = \max_{\overline{v} \in \{-1,1\}^k} X_j^\top X_S \left(X_S^\top X_S\right)^{-1}\overline{v},
$$

showing the equivalence between the two assumptions. $\qquad\square$

Remark 5. *One may require that the design is "normalized" so that $R_{i,i} = 1$, namely its columns have unit Euclidean norm. Under this normalization, one can check that R satisfies* (Irrep.) *of order $K = 1$. Hence, up to some normalization, one can always assume* (Irrep.) *of order $K = 1$.*

Remark 6. *When computing the LARS path, one has to compute the values*

$$
X_j^\top X_{\overline{S}^k}\left(X_{\overline{S}^k}^\top X_{\overline{S}^k}\right)^{-1}\varepsilon^k,
$$

see for instance Algorithm 3 or Algorithm 4, where these values are given by θ as shown by Proposition 6. It implies that, in practice, along the LARS path, one witnesses the maximal order K for which Irrepresentable Check ($\mathscr{A}_{\mathrm{Irr}}$) holds.

2.4. Variance Estimates

In our analysis, we introduce two independent estimates of the variance, namely $\widehat{\sigma}^2_{\mathrm{select}}$ to select the model and $\widehat{\sigma}^2_{\mathrm{test}}$ to perform post-selection test. The *budget* devoted to estimation of the variance is $n - (K+1)$ and we can divide it equitably into n_1 and n_2, namely

$$
n = n_1 + n_2 + (K + 1) \quad \text{with} \quad |n_1 - n_2| \geq 1.
$$

Let us fix, for the moment $j_1, \ldots, j_{K+1}$ the indexes that are putative indices for the selected variables. Let $P_{K+1}^\perp$ be the orthogonal projector on the orthogonal to $X_{j_1}, \ldots, X_{j_{K+1}}$. For ℓ positive define $V_\ell := \mathrm{Span}(e_1, \ldots, e_\ell)$ where e_i is the *ith* vector of the canonical basis. It is easy to check that we can find some ℓ such that

$$
E_1 := P_{K+1}^\perp(V_\ell) \text{ has dimension } n_1.
$$

We set also

$$
E_2 := E_1^\perp \cap (\mathrm{Span}(X_{j_1}, \ldots, X_{j_{K+1}}))^\perp \text{ that has dimension } n_2
$$

16

and

$$\widehat{\sigma}_{\text{select}}^{j_1,\dots,j_{K+1}} := \frac{||P_{E_1}Y||_2}{\sqrt{n_1}} \quad , \quad \widehat{\sigma}_{\text{test}}^{j_1,\dots,j_{K+1}} := \frac{||P_{E_2}Y||_2}{\sqrt{n_2}}. \tag{2.13}$$

By a small abuse of notation, we can index the estimator above by *signed* indexes $i_1,\dots,i_{K+1}$. Eventually we set

$$\widehat{\sigma}_{\text{select}} := \widehat{\sigma}_{\text{select}}^{\bar{\iota}_1,\dots,\bar{\iota}_{K+1}} \quad \text{and} \quad \widehat{\sigma}_{\text{test}} := \widehat{\sigma}_{\text{test}}^{\bar{\iota}_1,\dots,\bar{\iota}_{K+1}},$$

the estimates of the standard deviation σ.

2.5. Admissible Selection Procedures

Note that choosing a model $\widehat{S}$ is equivalent to choosing a model size $\widehat{m}$ so that

$$\widehat{S} = \left\{ \bar{\iota}_1, \bar{\iota}_2, \dots, \bar{\iota}_{\widehat{m}} \right\}. \tag{2.14}$$

Our procedure is flexible on this point and it allows any choice of $\widehat{m}$ as long as the following property ($\mathscr{A}_{\text{Stop}}$) is satisfied

> **Stopping Rule:** *The estimated model size $\widehat{m}$ is a "stopping time": $\widehat{m} \in [K-1]$ and*
>
> $\mathbb{1}_{\{\widehat{m} \leq a\}}$ *is a measurable function of* $(\lambda_1,\dots,\lambda_a,\widehat{\iota}_1,\dots,\widehat{\iota}_{K+1},\widehat{\sigma}_{\text{select}})$,
> $$(\mathscr{A}_{\text{Stop}})$$
> *for all $a \in [K-1]$.*

In other words, the decision to select a model of size $\{\widehat{m} = a\}$ depends only on the first a variables entering LARS and on $\widehat{\sigma}_{\text{select}}$. Of course, when σ^2 is known, $\widehat{\sigma}_{\text{select}}$ can be removed from ($\mathscr{A}_{\text{Stop}}$).

Remark 7. *Let us give an example to show that ($\mathscr{A}_{\text{Stop}}$) implies some restriction. Suppose, for example, that we want to decide wether the target β^0 is two sparse or one sparse. A natural decision rule is to look at large values of the second knot λ_2, if "$\lambda_2 > $ (some threshold)" chose $m = 2$ otherwise $m = 1$. This rule does not meet ($\mathscr{A}_{\text{Stop}}$), since looking at λ_2 we can choose only sizes m greater or equal to 2.*

In the sequel, we will present some examples of such "*stopping time*" procedures, see Section 4.1.

Denote by $P_k(Y)$ (resp. $P_k^{\perp}(Y)$) the orthogonal projection of the observation Y onto H_k (resp. the orthogonal of H_k) for all $k \geq 1$ where H_k are defined by (2.8). A class of selection procedures satisfying ($\mathscr{A}_{\text{Stop}}$) is given by

$$\mathbb{1}_{\{\widehat{m} \leq a\}} = h(P_a(Y), \widehat{\sigma}_{\text{select}}),$$

where h is any measurable function. These procedures decide to stop at $\{\widehat{m} = a\}$ based on the information given by $P_a(Y)$.

Once one has selected a model of size $\widehat{m}$, one may be willing to test if $\widehat{S}$ contains the true support S^0 by considering the null hypothesis

$$\mathbb{H}_0 : \text{``} S^0 \subseteq \widehat{S} \text{''},$$

namely there is no *false negatives*. Equivalently, one aim at testing the null hypothesis

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_{\widehat{m}} \text{''}, \tag{2.15}$$

at an exact significance level $\alpha \in (0, 1)$, where $(H_a)_{a=0}^{K-1}$ is defined by (2.8).

3. Exact Controls using Least Angle Regression: Main Results

3.1. Key notion: the "frozen" knots, their means and variances

3.1.1. Frozen knots

Given K as defined in (2.9) and fixed $i_1, \ldots, i_{K+1} \in [2p]$, one may define

$$\forall j \text{ s.t. } \theta_j(i_1, \ldots, i_k) \neq 1, \quad Z_j^{(i_1,\ldots,i_k)} := \frac{Z_j - \Pi_{i_1,\ldots,i_k}(Z_j)}{1 - \theta_j(i_1, \ldots, i_k)}, \tag{3.1}$$

where

$$\Pi_{i_1,\ldots,i_k}(Z_j) := \left(R_{j,i_1} \cdots R_{j,i_k} \right) M_{i_1,\ldots,i_k}^{-1} (Z_{i_1}, \ldots, Z_{i_k}) \tag{3.2}$$

and θ is given by (2.10). When $\mathbb{E}Z = 0$, one may remark that $\Pi_{i_1,\ldots,i_k}(Z_j)$ is the *regression* of Z_j on the vector $(Z_{i_1}, \cdots, Z_{i_k})$ whose variance-covariance matrix is $\sigma^2 M_{i_1,\ldots,i_k}$, namely

When $\mathbb{E}Z = 0$, $\quad \Pi_{i_1,\ldots,i_k}(Z_j) = \left(R_{j,i_1} \cdots R_{j,i_k} \right) M_{i_1,\ldots,i_k}^{-1} (Z_{i_1}, \ldots, Z_{i_k}) = \mathbb{E}\left[Z_j | Z_{i_1}, \cdots, Z_{i_k} \right].$

From this point, we can introduce

$$\forall k \geq 0, \quad \lambda_{k+1}^{(i_1,\ldots,i_k)} := \max_{j : \theta_j(i_1,\ldots,i_k) < 1} Z_j^{(i_1,\ldots,i_k)}, \tag{3.3}$$

and we emphasize that

$$\forall k \geq 0, \quad \lambda_{k+1} \mathbb{1}_{\{\widehat{i}_1 = i_1, \ldots, \widehat{i}_k = i_k\}} = \lambda_{k+1}^{(i_1,\ldots,i_k)} \mathbb{1}_{\{\widehat{i}_1 = i_1, \ldots, \widehat{i}_k = i_k\}}, \tag{3.4}$$

as proven in Appendix A.3 (Eq. (A.3)) and Proposition 8. We are now able to define the "*frozen*" values of the knots by

$$\lambda_1^f := Z_{i_1}, \ldots, \lambda_{K+1}^f := Z_{i_{K+1}}^{i_1,\ldots i_K}. \tag{3.5}$$

They are the Gaussian random variables that coincide with $\lambda_1, \lambda_2, \cdots, \lambda_{K+1}$ when the random indices $\widehat{i}_1, \widehat{i}_2, \ldots, \widehat{i}_{K+1}$ take the particular values $i_1, i_2, \ldots, i_{K+1}$.

18

Remark 8. *An interesting feature of the LARS knots is that they have a simple expression with respect to the partition given by the identity*

$$\sum_{(i_1,\ldots,i_K)\in\mathscr{A}_K} \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_K=i_K\}} = 1 \quad \textit{almost surely}.$$

As we have seen in (3.5)*, it holds that*

$$\forall k \in [K], \quad \lambda_k = \sum_{(i_1,\ldots,i_k)\in\mathscr{A}_k} \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}} \underbrace{Z_{i_k}^{i_1\ldots i_{k-1}}}_{=:\lambda_k^f},$$

giving the definition of the frozen knots λ_k^f above.

3.1.2. Mean and centering of the frozen knots

Now, denote

$$\forall y \in \mathbb{R}^n, \quad P^{(i_1,\ldots,i_k)}(y) = \left(X_{j_1}\cdots X_{j_k}\right)M_{j_1,\ldots,j_k}^{-1}(X_{j_1}^\top,\ldots,X_{j_k}^\top)y \qquad (3.6)$$

the orthogonal projection of y onto $\mathrm{Span}(X_{j_1},\ldots,X_{j_k})$. Recall that P_k is the orthogonal projection onto H_k which is a random subspace. Recall also that, conditional on the event $\{\widehat{\imath}_1 = i_1,\ldots,\widehat{\imath}_k = i_k\}$ the subspace H_k is fixed. Note that

$$P_k \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}} = P^{(i_1,\ldots,i_k)} \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}},$$

$$P_k^\perp \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}} = \left(\mathrm{Id}_n - P^{(i_1,\ldots,i_k)}\right)\mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}},$$

$$\text{and for all } i \in [2p], \quad \Pi_{i_1,\ldots,i_k}(Z_i) = s\langle X_j, P^{(i_1,\ldots,i_k)}(Y)\rangle,$$

where $i = j + p(1-s)/2$. The mean m_k^f and standard deviation $\sigma\rho_k^f$ of λ_k^f are important values defined for all $k \in [K]$,

$$m_k \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}} = m_k^f \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}},$$

$$\rho_k \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}} = \rho_k^f \mathbb{1}_{\{\widehat{\imath}_1=i_1,\ldots,\widehat{\imath}_k=i_k\}},$$

with

$$m_k^f = \frac{s_k\langle X_{j_k}, \left(\mathrm{Id}_n - P^{(i_1,\ldots,i_{k-1})}\right)X\beta^0\rangle}{1 - \theta_{i_k}(i_1,\ldots,i_{k-1})}, \qquad (3.7)$$

$$\rho_k^f = \frac{\sqrt{\langle X_{j_k}, \left(\mathrm{Id}_n - P^{(i_1,\ldots,i_{k-1})}\right)X_{j_k}\rangle}}{1 - \theta_{i_k}(i_1,\ldots,i_{k-1})}, \qquad (3.8)$$

and this definition is equivalent to (3.12) and (3.13), see Section 3.2. Recall that $\overline{\mu}^0 = \overline{R}\beta^0$ as defined in (2.3) and note that

$$m_k^f = 0 \quad \Longleftrightarrow \quad \overline{\mu}_{i_k}^0 - \Pi_{i_1,\ldots,i_{k-1}}(\overline{\mu}_{i_k}^0) = 0 \quad \Longleftrightarrow \quad \langle X_{j_k}, \left(\mathrm{Id}_n - P^{(i_1,\ldots,i_{k-1})}\right)X\beta^0\rangle = 0, \qquad (3.9)$$

which is implied when *the true support S^0 of β^0 is included in $\overline{S}^k$*, defined by (2.6). It shows the next proposition.

19

Proposition 7. *For fixed $0 \leq a \leq K-1$, conditional on the selection event $\{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K\}$, the hypothesis*

$$\mathbb{H}_0 : \text{ "} X\beta^0 \in H_a \text{"}$$

implies that $m_k^f = 0$ for all $a < k \leq K$, namely $(Z_{i_{a+1}}^{(i_1,\ldots,i_a)}, \ldots, Z_{i_K}^{(i_1,\ldots,i_{K-1})})$ is centered.

This proposition is important to define the hypothesis under consideration, see also Remark 1.

3.1.3. One key result: characterization of the selection event

Regarding the joint law of *frozen* knots, one has the following important proposition whose proof can be found in Section C.1.

Proposition 8. *Let $(i_1, \ldots, i_K, i_{K+1}) \in \mathscr{A}_{K+1}$, namely a fixed active set of size $K+1$.*

- *It holds that*

$$(Z_j^{(i_1,\ldots,i_{k+1})})_{j \neq i_1,\ldots,i_{k+1}} \perp\!\!\!\perp Z_{i_{k+1}}^{(i_1,\ldots,i_k)} \perp\!\!\!\perp Z_{i_k}^{(i_1,\ldots,i_{k-1})} \perp\!\!\!\perp \cdots \perp\!\!\!\perp Z_{i_2}^{(i_1)} \perp\!\!\!\perp Z_{i_1}$$

are mutually independent, for any $k \in [K]$. And it holds that

$$\widehat{\sigma}_{\text{select}}^{i_1,\ldots,i_{K+1}} \perp\!\!\!\perp \widehat{\sigma}_{\text{test}}^{i_1,\ldots,i_{K+1}} \perp\!\!\!\perp Z_{i_{K+1}}^{(i_1,\ldots,i_K)} \perp\!\!\!\perp Z_{i_K}^{(i_1,\ldots,i_{K-1})} \perp\!\!\!\perp \cdots \perp\!\!\!\perp Z_{i_2}^{(i_1)} \perp\!\!\!\perp Z_{i_1} . \qquad (3.10)$$

- *If $(i_1, \ldots, i_K)$ satisfies $(\mathscr{A}_{\text{Irr.}})$ then*

$$\begin{aligned}
&\{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_{k+1} = i_{k+1}\} \\
&= \{\lambda_{k+1}^{(i_1,\ldots,i_k)} = Z_{i_{k+1}}^{(i_1,\cdots,i_k)} \leq Z_{i_k}^{(i_1,\cdots,i_{k-1})} \leq \cdots \leq Z_{i_2}^{(i_1)} \leq Z_{i_1}\} \\
&= \{\lambda_{k+1}^{(i_1,\ldots,i_k)} = Z_{i_{k+1}}^{(i_1,\cdots,i_k)} \leq Z_{i_k}^{(i_1,\cdots,i_{k-1})} \leq \cdots \leq Z_{i_{a+1}}^{(i_1,\cdots,i_a)} \leq Z_{i_a}^{(i_1,\cdots,i_{a-1})} = \lambda_a^{(i_1,\ldots,i_{a-1})}\} \\
&\bigcap \{\lambda_{k+1} = Z_{i_{k+1}}^{(i_1,\cdots,i_k)}, \ldots, \lambda_a = Z_{i_a}^{(i_1,\cdots,i_{a-1})}\} \\
&\bigcap \{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_a = i_a\},
\end{aligned}$$

for any $0 \leq a < k \leq K$ with the convention $\lambda_0 = \infty$.

From Proposition 8, we know that *frozen* values of the knots $Z_{i_1}, Z_{i_2}^{(i_1)}, \cdots, Z_{i_K}^{(i_1,\ldots,i_{K-1})}, Z_{i_{K+1}}^{(i_1,\ldots,i_K)}$ are independent with Gaussian distribution. The properties above are the basis of our reasoning. Remark that if we condition by $\lambda_{K+1}^f = \ell_{K+1}$, because of the independence above, the distribution of the other *frozen* variables $Z_{i_1}, Z_{i_2}^{(i_1)}, \cdots, Z_{i_K}^{(i_1,\ldots,i_{K-1})}$ and $\widehat{\sigma}_{\text{select}}^{i_1,\ldots,i_{K+1}}, \widehat{\sigma}_{\text{test}}^{i_1,\ldots,i_{K+1}}$ remain unchanged.

Proposition 9. *Assume that the design X is such that Irrepresentable Condition* (Irrep.) *of order K holds. Almost surely, one has*

- *Among all possible sets $(i_1, \ldots, i_K) \in \mathscr{A}_K$, there is one and only one such that*

$$\max_{i_{K+1} \neq i_1, \ldots, i_K} Z_{i_{K+1}}^{(i_1, \cdots, i_K)} \leq Z_{i_K}^{(i_1, \cdots, i_{K-1})} \leq \cdots \leq Z_{i_2}^{(i_1)} \leq Z_{i_1}; \qquad (3.11)$$

- *this set is the selected set by LARS, namely $\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K$;*
- *and it holds for all $(i_1, \ldots, i_K) \in \mathscr{A}_K$,*

$$\mathbb{P}\big(\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K\big) = \mathbb{P}\Big(\max_{i_{K+1} \neq i_1, \ldots, i_K} Z_{i_{K+1}}^{(i_1, \cdots, i_K)} \leq Z_{i_K}^{(i_1, \cdots, i_{K-1})} \leq \cdots \leq Z_{i_2}^{(i_1)} \leq Z_{i_1}\Big).$$

Proof. Note that (Irrep.) implies $(\mathscr{A}_{\mathrm{Irr.}})$ by Proposition 6. Then apply the second point of Proposition 8 to conclude. $\qquad\square$

Finding the set $\{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K\}$ selected by LARS may be related to a combinatorial search testing (3.11) among all possible candidates $(i_1, \ldots, i_K) \in \mathscr{A}_K$. Under *Irrepresentable Condition*, this support selected by LARS is given by (3.11) which can be seen as the extension of (1.2) introducing **[Q1]** in Section 1.2.

3.2. Main results: joint law and post-selection tests construction

We assume that K is defined as in (2.9). Except in Section 3.4, σ^2 is assumed to be *known*. Let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ be the first *signed* variables entering along the LARS path. In this section, we are interested in the joint law of the LARS knots $(\lambda_1, \ldots, \lambda_K)$ conditional on λ_{K+1} and $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$. To define this joint law, we need to precise the centering parameters m_k by (see also (3.7))

$$m_k := \frac{\mu_{\widehat{\imath}_k}^0 - \big(R_{\widehat{\imath}_k, \widehat{\imath}_1} \cdots R_{\widehat{\imath}_k, \widehat{\imath}_{k-1}}\big) M_{\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}}^{-1} \big(\mu_{\widehat{\imath}_1}^0, \cdots, \mu_{\widehat{\imath}_{k-1}}^0\big)}{1 - \theta_{\widehat{\imath}_k}^{k-1}}, \qquad (3.12)$$

the first standard deviation $\sigma \rho_1$ with $\rho_1 := \sqrt{R_{\widehat{\imath}_1, \widehat{\imath}_1}}$, and the others $\sigma \rho_k$ by (see also (3.8))

$$\rho_\ell := \frac{\sqrt{R_{\widehat{\imath}_\ell, \widehat{\imath}_\ell} - \big(R_{\widehat{\imath}_\ell, \widehat{\imath}_1} \cdots R_{\widehat{\imath}_\ell, \widehat{\imath}_{\ell-1}}\big) M_{\widehat{\imath}_1, \ldots, \widehat{\imath}_{\ell-1}}^{-1} \big(R_{\widehat{\imath}_\ell, \widehat{\imath}_1}, \cdots, R_{\widehat{\imath}_\ell, \widehat{\imath}_{\ell-1}}\big)}}{1 - \theta_{\widehat{\imath}_\ell}^{\ell-1}} \quad \text{for } 2 \leq \ell \leq K+1,$$

$$(3.13)$$

where

$$\theta^{\ell-1} := \theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{\ell-1}), \quad \text{for } 2 \leq \ell \leq K+1,$$

is defined by (2.10) and $M_{\widehat{\imath}_1, \ldots, \widehat{\imath}_{\ell-1}}$ is defined by (2.11).

3.2.1. Proof of Theorem 2

From the definition of the Gaussian random variable $Z_{i_k}^{(i_1,\dots,i_{k-1})}$ in (3.1) one can deduce that its mean m_k is given by (3.12) and its standard deviation v_k by (3.13), considering putative indices for the selected variables. Furthermore by the first point of Proposition 8 we know that these variables are independent. We deduce that their joint density $(Z_{i_1}, Z_{i_2}^{(i_1)}, \dots, Z_{i_K}^{(i_1,\dots,i_{K-1})})$ is

$$\prod_{k=1}^{K} \varphi_{m_k, v_k^2}(\ell_k),$$

with respect to the Lebesgue measure. Now, we are conditional on

$$\mathcal{E} := \{\widehat{\imath}_1 = i_1, \dots, \widehat{\imath}_K = i_K, \widehat{\imath}_{K+1} = i_{K+1}, \lambda_{K+1}\},$$

and $(i_1, \dots, i_K)$ satisfies ($\mathcal{A}_{\mathrm{Irr}}$), Proposition 8 implies $\mathcal{E} = \{\lambda_{K+1} \leq Z_{i_K}^{(i_1,\dots,i_{K-1})} \leq \cdots \leq Z_{i_1}\}$, and *on this event $\mathcal{E}$* it holds

$$(Z_{i_1}, Z_{i_2}^{(i_1)}, \dots, Z_{i_K}^{(i_1,\dots,i_{K-1})}) = (\lambda_1, \lambda_2, \dots, \lambda_K). \tag{3.14}$$

Conditional on $\mathcal{E}$, the joint density of $(Z_{i_1}, Z_{i_2}^{(i_1)}, \dots, Z_{i_K}^{(i_1,\dots,i_{K-1})})$ is proportional to

$$\left(\prod_{k=1}^{K} \varphi_{m_k, v_k^2}(\ell_k)\right) \mathbb{1}_{\{\ell_1 \geq \ell_2 \geq \cdots \geq \ell_K \geq \lambda_{K+1}\}}, \tag{3.15}$$

with respect to the Lebesgue measure and by (3.14) it is the conditional density of the knots. Since this conditional density does not depend on i_{K+1}, one can de-condition on $\widehat{\imath}_{K+1}$.

3.2.2. Construction of the Generalized Spacing test

A useful consequence of Theorem 2 is that one can explicitly describe the joint law of the LARS knots after having selected a support $\widehat{S}$ of size $\widehat{m}$ with any procedure satisfying ($\mathcal{A}_{\mathrm{Stop}}$). In the sequel, we denote

$$F_i := \Phi_i(\lambda_i) := \Phi\left(\frac{\lambda_i}{\sigma \rho_i}\right) \quad \text{and} \quad \mathcal{P}_{i,j} := \Phi_i \circ \Phi_j^{-1}, \quad \text{for } i, j \in [K+1], \tag{3.16}$$

where $\lambda_0 = \infty$ and $F_0 = 1$ by convention.

Proposition 10. *Let $a \in \mathbb{N}$ be such that $0 \leq a \leq K-1$. Let $\widehat{m}$ be a selection procedure satisfying ($\mathcal{A}_{\mathrm{Stop}}$). Under the conditions of Theorem 2, under the null hypothesis*

$$\mathbb{H}_0 : \text{``}X\beta^0 \in H_a\text{''}, \tag{3.17}$$

22

and conditional on the selection event $\left\{\widehat{m} = a, F_a, F_{K+1}, \widehat{\iota}_1, \ldots, \widehat{\iota}_K, \widehat{\iota}_{K+1}\right\}$, $(F_{a+1}, \ldots, F_K)$ is uniformly distributed on

$$\mathscr{D}_{a+1,K} := \big\{ (f_{a+1}, \ldots, f_K) \in \mathbb{R}^{K-a} :$$
$$\mathscr{P}_{a+1,a}(F_a) \geq f_{a+1} \geq \mathscr{P}_{a+1,a+2}(f_{a+2}) \geq \cdots \geq \mathscr{P}_{a+1,K}(f_K) \geq \mathscr{P}_{a+1,K+1}(F_{K+1}) \big\},$$

where $\mathscr{P}_{i,j}$ are described in (3.16).

A proof of this corollary can be found in Appendix C.2.

Remark 9. *The previous statement is consistent with the case $a = 0$ corresponding to the* global null *hypothesis* $\mathbb{H}_0 : \text{``}X\beta^0 = 0\text{''}$ *(or equivalently $\mathbb{E}Z = 0$). Therefore, if Z is centered then, conditional on F_{K+1}, $(F_1, \ldots, F_K)$ is uniformly distributed on*

$$\mathscr{D}_{1,K} := \big\{ (f_1, \ldots, f_K) \in \mathbb{R}^K : 1 \geq f_1 \geq \mathscr{P}_{1,2}(f_2) \geq \cdots \geq \mathscr{P}_{1,K}(f_K) \geq \mathscr{P}_{1,K+1}(F_{K+1})) \big\}.$$

Remark 10. *In the orthogonal case where $\overline{R} = \text{Id}$, note that $\theta_j(i_1, \ldots, i_\ell) = 0$ for all $\ell \geq 1$ and all $i_1, \ldots, i_\ell \neq j$, $\rho_j = 1$ and $\mathscr{P}_{i,j}(f) = f$. We recover that $\mathscr{D}_{1,K}$ is the set of order statistics*

$$1 \geq f_1 \geq f_2 \geq \ldots \geq f_K \geq \Phi(\lambda_{K+1}/\sigma).$$

In this case, the knots λ_i are Gaussian order statistics $\lambda_1 = Z_{\widehat{\iota}_1} \geq \lambda_2 = Z_{\widehat{\iota}_2} \geq \ldots \geq \lambda_K = Z_{\widehat{\iota}_K} \geq \lambda_{K+1}$ of the vector Z.

From Theorem 2, we deduce several testing statistics. To this end, we introduce some notation. Define

$$\mathscr{I}_{ab}(s,t) := \int_{\mathscr{P}_{(a+1),b}(t)}^{\mathscr{P}_{(a+1),a}(s)} \mathrm{d}f_{a+1} \int_{\mathscr{P}_{(a+2),b}(t)}^{\mathscr{P}_{(a+2),(a+1)}(f_{a+1})} \mathrm{d}f_{a+2} \int_{\mathscr{P}_{(a+3),b}(t)}^{\mathscr{P}_{(a+3),(a+2)}(f_{a+2})} \mathrm{d}f_{a+3} \cdots \int_{\mathscr{P}_{(b-1),b}(t)}^{\mathscr{P}_{(b-1),(b-2)}(f_{b-2})} \mathrm{d}f_{b-1}$$

$$\tag{3.18}$$

for $0 \leq a < b$ and $s, t \in \mathbb{R}$, with the convention that $\mathscr{I}_{ab} = 1$ when $b = a + 1$,

and also

$$\mathbb{F}_{abc}(t) := \mathbb{1}_{\{\lambda_c \leq t \leq \lambda_a\}} \int_{\Phi_b(\lambda_c)}^{\Phi_b(t)} \mathscr{I}_{ab}(F_a, f_b) \mathscr{I}_{bc}(f_b, F_c) \mathrm{d}f_b \tag{3.19}$$

for $0 \leq a < b < c \leq K+1$, $t \in \mathbb{R}$ where $F_a = \Phi_a(\lambda_a)$ and $F_c = \Phi_c(\lambda_c)$.

Remark 11. *On the numerical side, note that this quantity can be computed using Quasi Monte Carlo (QMC) methods as in (Genz and Bretz, 2009, Chapter 5.1) or Appendix D. The function $\mathbb{F}_{abc}$ gives the CDF of λ_b conditional on λ_a, λ_c and on some selection event, as shown in the next proposition.*
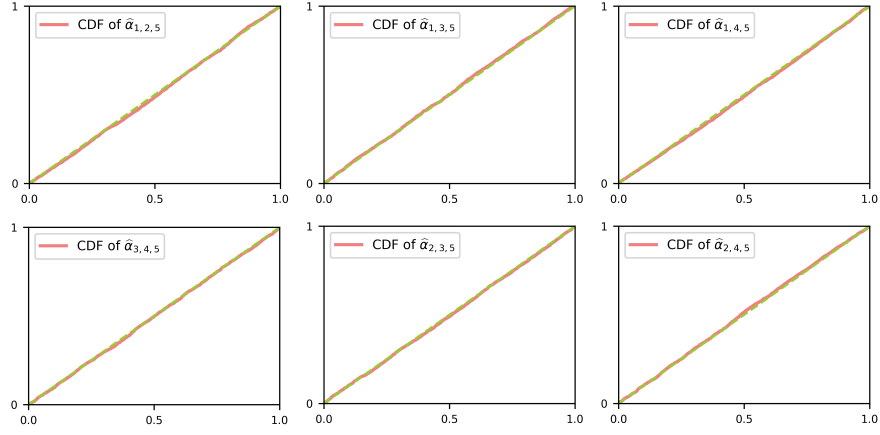

Figure 2: Observed empirical law of $\widehat{\alpha}_{abc}$ over 5,000 Monte-Carlo repetitions with $n = 200$ and $p = 300$. We considered a design $X \in \mathbb{R}^{n \times p}$ with independent column vectors uniformly distributed on the sphere and an independent $y \in \mathbb{R}^n$ with i.i.d. standard Gaussian entries, and we computed the indexes $(\widehat{\imath}_1, \ldots, \widehat{\imath}_n)$ and the knots $(\lambda_1, \ldots, \lambda_n)$ entering the model with LARS. The displays are the empirical CDF of the $\widehat{\alpha}_{abc}$. We observe a perfect fit with the uniform distribution: the conditional law of the LARS knots obtained theoretically is numerically validated.

Proposition 11. *Let a, b, c be such that $0 \le a < b < c \le K + 1$. Let $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ be the first knots and let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$ and $\widehat{m}$ is chosen according to a procedure satisfying $(\mathscr{A}_{\mathrm{Stop}})$ then under the null hypothesis*

$$\mathbb{H}_0 \, : \, \text{``} X\beta^0 \in H_a \text{''},$$

it holds that

$$\mathbb{P}\big[\lambda_b \le t \mid \widehat{m} = a, \lambda_a, \lambda_c, \widehat{\imath}_{a+1}, \ldots, \widehat{\imath}_{c-1}\big] = \frac{\mathbb{F}_{abc}(t)}{\mathbb{F}_{abc}(\lambda_a)}. \tag{3.20}$$

A proof of this proposition can be found in Appendix C.3.

Remark 12. *Note that the deterministic choice $\widehat{m} = a$, for a fixed $a \in [K - 1]$, is a procedure satisfying $(\mathscr{A}_{\mathrm{Stop}})$ and Proposition 11 holds true. It shows that if $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$ then, under the null hypothesis $\mathbb{H}_0 \, : \, \text{``} X\beta^0 \in H_a \text{''}$, it holds that*

$$\mathbb{P}\big[\lambda_b \le t \mid \lambda_a, \lambda_c, \widehat{\imath}_{a+1}, \ldots, \widehat{\imath}_{c-1}\big] = \frac{\mathbb{F}_{abc}(t)}{\mathbb{F}_{abc}(\lambda_a)}, \tag{3.21}$$

for any $0 \le a < b < c \le K + 1$.

3.2.3. Proof of Theorem 3

From Proposition 11 we know that under $\mathbb{H}_0$ and conditional on the selection event $\{\widehat{m} = a\}$, Eq. (3.20) gives the conditional cumulative distribution function of λ_b. As a consequence and under the same conditioning, one has

$$\frac{\mathbb{F}_{abc}(\lambda_b)}{\mathbb{F}_{abc}(\lambda_a)} \sim \mathscr{U}(0,1).$$

Finally considerations of distribution under the alternative show that, to obtain a p-value, we must consider the complement to 1 of the quantity above.

3.2.4. Montecarlo simulations, Spacing tests, and Generalized Spacing tests.

Theorem 3 can be numerically illustrated in Figure 2. Note that we have a perfect fit with the uniform law: the conditional law of the LARS knots obtained theoretically is numerically validated[4].

This testing statistic generalizes previous testing statistics that appeared in "Spacing Tests", as presented in (Tibshirani et al., 2015, Chapter 5) for instance, and will be referred to as the *Generalized Spacing test*.

Remark 13. *If one considers $a = 0$, $b = 1$ and $c = 2$ then one gets*

$$\widehat{\alpha}_{012} = 1 - \frac{\Phi_1(\lambda_1) - \Phi_1(\lambda_2)}{\Phi_1(\lambda_0) - \Phi_1(\lambda_2)} = \frac{1 - \Phi_1(\lambda_1)}{1 - \Phi_1(\lambda_2)}.$$

Similarly, taking $b = a + 1$ and $c = a + 2$ one gets

$$\widehat{\alpha}_{a(a+1)(a+2)} = \frac{\Phi_{a+1}(\lambda_{a+1}) - \Phi_{a+1}(\lambda_a)}{\Phi_{a+1}(\lambda_{a+2}) - \Phi_{a+1}(\lambda_a)}.$$

which is the conservative spacing test, see (Tibshirani et al., 2016, Theorem 2).

3.3. Exact false negative testing after model selection

We get back to the *general design* case. Given $\alpha \in (0,1)$ and using Theorem 3, one can consider the following *exact* testing procedure at level α on false negatives, see the pseudo-code in Algorithm 2. The theoretical guarantee of this algorithm is given by the next proposition. It shows that conditional on the event that *there is no false negatives*, namely "$X\beta^0 \in H_{\widehat{m}}$", the observed significance $\widehat{\alpha}$ has uniform law and hence $\mathbb{1}_{\{\widehat{\alpha} \leq \alpha\}}$ is a testing procedure with level exactly α.

---

[4]A reproducible experience given in a Python notebook is available at `https://github.com/ydecastro/lar_testing/blob/master/Law_LAR.ipynb`

Corollary 12. *Let $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ be the first knots and let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$ and $\widehat{m}$ is chosen according to a procedure satisfying $(\mathscr{A}_{\mathrm{Stop}})$ then conditional on the null hypothesis*

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_{\widehat{m}} \text{''},$$

it holds that

$$\widehat{\alpha}_{\widehat{m}(\widehat{m}+1)(K+1)} := 1 - \frac{\mathbb{F}_{\widehat{m}(\widehat{m}+1)(K+1)}(\lambda_{\widehat{m}+1})}{\mathbb{F}_{\widehat{m}(\widehat{m}+1)(K+1)}(\lambda_{\widehat{m}})} \sim \mathscr{U}(0,1),$$

namely, it is uniformly distributed over $(0,1)$.

Proof. By Theorem 3, the conditional law of $\widehat{\alpha}_{a(a+1)(K+1)}$ when $\{\widehat{m} = a\}$. Remark the conditional law (1.3) does not depend on a, $b = a+1, c = K+1$, hence this law is unconditional on $\widehat{m}$. $\qquad\square$

When the variance σ^2 is unknown, one can "Studentized" this test as presented in the next section. The reader may consult Section 3.4 for a definition and check that the quantities $\widehat{\beta}_{abc}, \widetilde{\mathbb{F}}, \Lambda_k$ do not require σ to be computed.

Corollary 13. *Let $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ be the first knots and let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$ and $\widehat{m}$ is chosen according to a procedure satisfying $(\mathscr{A}_{\mathrm{Stop}})$ then conditional on the null hypothesis*

$$\mathbb{H}_0 : \text{``} X\beta^0 \in H_{\widehat{m}} \text{''},$$

it holds that

$$\widehat{\beta}_{\widehat{m}(\widehat{m}+1)(K+1)} := 1 - \frac{\widetilde{\mathbb{F}}_{\widehat{m}(\widehat{m}+1)(K+1)}(\Lambda_{\widehat{m}+1})}{\widetilde{\mathbb{F}}_{\widehat{m}(\widehat{m}+1)(K+1)}(\Lambda_{\widehat{m}})} \sim \mathscr{U}(0,1),$$

namely, it is uniformly distributed over $(0,1)$.

Proof. By Theorem 4, the conditional law of $\widehat{\beta}_{a(a+1)(K+1)}$ when $\{\widehat{m} = a\}$. Remark the conditional law (3.24) does not depend on a, $b = a+1, c = K+1$, hence this law is unconditional on $\widehat{m}$. $\qquad\square$

3.4. Exact Testing Procedure on False Negatives with Variance Estimation

From the result of Section 3.2, one can present a method to select a model and propose an exact test on false negatives in the *general design case* when the variance is *unknown*. We introduce a new *exact* testing procedure that can be deployed when $(\mathscr{A}_{\mathrm{Stop}})$ holds, namely an *"admissible"* selection procedure is used to build $\widehat{S}$. We start by a preliminary result.

Proposition 14. *Let $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ be the first knots of LARS and let $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \widehat{\imath}_{K+1})$ be the first variables entering along the LARS path. If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ satisfies Condition $(\mathscr{A}_{\mathrm{Irr.}})$ then conditional on $\{\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \widehat{\imath}_{K+1}, \lambda_{K+1}\}$*

- *the random variables $\big((\lambda_1,\ldots,\lambda_K),\widehat{\sigma}_{\text{select}},\widehat{\sigma}_{\text{test}}\big)$ are independent;*
- *and, under the null hypothesis $\mathbb{H}_0$: "$X\beta^0 \in H_K$", the distribution of $(\lambda_1,\ldots,\lambda_K)$ is given by Theorem 2, the distribution of $\widehat{\sigma}_{\text{select}}$ and of $\widehat{\sigma}_{\text{test}}$ are $\sigma\chi(n_1)/\sqrt{n_1}$ and $\sigma\chi(n_2)/\sqrt{n_2}$ respectively, where the $\chi(d)$ distribution is defined as the square root of a $\chi^2(d)$ distribution.*

Remark 14. *Note that under the null hypothesis $\mathbb{H}_0$: "$X\beta^0 \in H_K$", the Gaussian vectors $P_{E_1}(Y)$ and $P_{E_2}(Y)$ (see (2.13)), defining the variance estimates $\widehat{\sigma}^2_{\text{select}}$ and of $\widehat{\sigma}^2_{\text{test}}$, are centered.*
This null hypothesis means that the true support is included in the set of the K first indices chosen by LARS. One may chose K large enough to guarantee this null hypothesis.

Proof of Proposition 14. Let us fix some values $i_1,\ldots,i_{K+1}$, we recall that the *frozen* values of the knots

$$\lambda_1^f := Z_{i_1},\ldots,\lambda_K^f := Z_{i_K}^{(i_1,\ldots i_{K-1})}, \lambda_{K+1}^f := Z_{i_{K+1}}^{(i_1,\ldots i_K)},$$

are Gaussian independent and

$$\widehat{\sigma}_{\text{select}}^{i_1,\ldots,i_{K+1}} \perp\!\!\!\perp \widehat{\sigma}_{\text{test}}^{i_1,\ldots,i_{K+1}} \perp\!\!\!\perp Z_{i_{K+1}}^{(i_1,\ldots,i_K)} \perp\!\!\!\perp Z_{i_K}^{(i_1,\ldots,i_{K-1})} \perp\!\!\!\perp \cdots \perp\!\!\!\perp Z_{i_2}^{(i_1)} \perp\!\!\!\perp Z_{i_1},$$

see Proposition 8 and (3.10). Let us condition by $\{\widehat{\imath}_1 = i_1,\ldots,\widehat{\imath}_K = i_K, \lambda_{K+1}^f = \ell_{K+1}\}$ because of the independence above, the distribution of $\widehat{\sigma}_{\text{select}}$ and $\widehat{\sigma}_{\text{test}}$ remain unchanged and independent of the other variables. By Remark 14, these standard deviation estimates are defined from centered Gaussian vectors and hence follow χ distributions. Furthermore on this event, $\lambda_h^f = \lambda_h$, $h \in [K+1]$ and by Proposition 8 this event is equivalent to

$$\{Z_{i_1} > \cdots > Z_{i_K}^{(i_1,\ldots i_{K-1})} > \lambda_{K+1} = \ell_{K+1}\}.$$

This implies that the conditional distribution is the one claimed. $\qquad\square$

Recall that, up to some positive numerical constant, the probability density function of the multivariate t-distribution with ν degrees of freedom, mean $m = (m_1,\ldots,m_K)$ and variance-covariance matrix $\text{Diag}(\rho_1,\ldots,\rho_K)$ is given by

$$\widetilde{\varphi}(t_1,\ldots,t_K) := \left[1 + \frac{1}{\nu}\sum_{k=1}^{K}\Big(\frac{t_k - m_k}{\rho_k}\Big)^2\right]^{-\frac{\nu+K}{2}}.$$

We have an analogue to Theorem 2 giving the joint law of

$$\Lambda_k := \frac{\lambda_k}{\widehat{\sigma}_{\text{test}}} \quad \text{for } k = 1,\ldots,K+1, \tag{3.22}$$

where $\widehat{\sigma}_{\text{test}}$ is given by (2.13) has n_2 degrees of freedom, see Proposition 14. In the sequel, we will consider that $\nu = n_2$ in the expression of $\widetilde{\varphi}$.

27

Theorem 15 (Conditional Joint Law of the Studentized LARS knots). *Let us consider* $(\lambda_1, \ldots, \lambda_K, \lambda_{K+1})$ *be the first knots and let* $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \widehat{\imath}_{K+1})$ *be the first variables entering along the LARS path.*

If $(\widehat{\imath}_1, \ldots, \widehat{\imath}_K)$ *satisfies* $(\mathscr{A}_{\mathrm{Irr.}})$ *then, under the null hypothesis* $\mathbb{H}_0$: *"* $X\beta^0 \in H_K$ *" and conditional on the selection event* $\{\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \Lambda_{K+1}\}$, *the vector* $(\Lambda_1, \ldots, \Lambda_K)$ *has law with density (w.r.t. the Lebesgue measure)*

$$\mathrm{P}_{(\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \Lambda_{K+1})}^{-1} \widetilde{\varphi}(t_1, \ldots, t_K) \mathbb{1}_{\{t_1 \geq t_2 \geq \cdots \geq t_K \geq \Lambda_{K+1}\}},$$

at point $(t_1, t_2, \ldots, t_K)$*, where* $\mathrm{P}_{(\widehat{\imath}_1, \ldots, \widehat{\imath}_K, \Lambda_{K+1})}$ *is a normalizing constant,* m_k *and* ρ_k *are as in* (3.12) *and* (3.13).

Proof of Theorem 15. Let us fix some values $i_1, \ldots, i_{K+1}$. From the definition of the Gaussian random variable $Z_{i_k}^{(i_1, \ldots, i_{k-1})}$ in (3.1) one can deduce that its mean m_k is given by (3.12) and its standard deviation $v_k := \sigma \rho_k$ by (3.13), considering putative indices for the selected variables. By the proof of Proposition 14, we know that these variables are independent of $\widehat{\sigma}_{\mathrm{test}}^{i_1, \ldots, i_{K+1}}$, which has $\sigma \frac{\chi(n_2)}{\sqrt{n_2}}$ distribution. We deduce that the vector $(Z_{i_1}, Z_{i_2}^{(i_1)}, \ldots, Z_{i_K}^{(i_1, \ldots, i_{K-1})})/\widehat{\sigma}_{\mathrm{test}}^{i_1, \ldots, i_{K+1}}$ has density a multivariate t-distribution with v degrees of freedom, mean $m = (m_1, \ldots, m_K)$ and variance-covariance matrix $\mathrm{Diag}(\rho_1, \ldots, \rho_K)$. Now recall that, conditional on

$$\mathscr{E} := \{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K, \widehat{\imath}_{K+1} = i_{K+1}, \lambda_{K+1}\},$$

and $(i_1, \ldots, i_K)$ satisfies $(\mathscr{A}_{\mathrm{Irr.}})$, Proposition 8 implies that $\mathscr{E} = \{\lambda_{K+1} \leq Z_{i_K}^{(i_1, \ldots, i_{K-1})} \leq \cdots \leq Z_{i_1}\}$ or equivalently

$$\mathscr{E} = \left\{ \Lambda_{K+1} \leq \frac{Z_{i_K}^{(i_1, \ldots, i_{K-1})}}{\widehat{\sigma}_{\mathrm{test}}^{i_1, \ldots, i_{K+1}}} \leq \cdots \leq \frac{Z_{i_1}}{\widehat{\sigma}_{\mathrm{test}}^{i_1, \ldots, i_{K+1}}} \right\}$$

and *on this event $\mathscr{E}$* it holds

$$(Z_{i_1}, Z_{i_2}^{(i_1)}, \ldots, Z_{i_{K+1}}^{(i_1, \ldots, i_K)}, \widehat{\sigma}_{\mathrm{test}}^{i_1, \ldots, i_{K+1}}) = (\lambda_1, \lambda_2, \ldots, \lambda_{K+1}, \widehat{\sigma}_{\mathrm{test}}).$$

Since this conditional density does not depend on i_{K+1}, one can de-condition on $\widehat{\imath}_{K+1}$. $\square$

For $0 \leq a < b \leq K+1$, we introduce

$$\widetilde{\varphi}_{ab}(t_{a+1}, \ldots, t_{b-1}) := \left[1 + \frac{1}{v} \sum_{k=a+1}^{b-1} \left(\frac{t_k}{\rho_k} \right)^2 \right]^{-\frac{v+b-a}{2}}$$

$$\widetilde{\mathscr{I}}_{ab}(s, t) := \int_{\{s \geq t_{a+1} \geq \cdots \geq t_{b-1} \geq t\}} \widetilde{\varphi}_{ab}(t_{a+1}, \ldots, t_{b-1}) \mathrm{d}t_{a+1} \cdots \mathrm{d}t_{b-1},$$

with the convention $\widetilde{\mathscr{I}}_{ab}(s,t) = 1$ when $b = a + 1$: and also

$$\widetilde{\mathbb{F}}_{abc}(t) := \mathbb{1}_{\{\Lambda_c \leq t \leq \Lambda_a\}} \int_{\Lambda_c}^{t} \widetilde{\mathscr{I}}_{ab}(\Lambda_a, \ell_b) \widetilde{\mathscr{I}}_{bc}(\ell_b, \Lambda_c) \left[1 + \frac{1}{\nu}\left(\frac{\ell_b}{\rho_b}\right)^2\right]^{-\frac{\nu+1}{2}} \mathrm{d}\ell_b \qquad (3.23)$$

for $0 \leq a < b < c \leq K+1$, $t \in \mathbb{R}$.

When $m_{a+1} = \cdots = m_{c-1} = 0$, the function $\widetilde{\mathbb{F}}_{abc}$ gives the CDF of Λ_b conditional on Λ_a, Λ_c and on some selection event, as shown below in Theorem 4 and (3.25).

For $0 \leq a < b < c \leq K+1$, we introduce the p-value

$$\widehat{\beta}_{abc} = \widehat{\beta}_{abc}(\lambda_a, \lambda_b, \lambda_c, \widehat{\imath}_1, \ldots, \widehat{\imath}_{K+1}, \widehat{\sigma}_{\text{test}}) = 1 - \frac{\widetilde{\mathbb{F}}_{abc}(\Lambda_b)}{\widetilde{\mathbb{F}}_{abc}(\Lambda_a)} \qquad (3.24)$$

On the numerical side, note that this quantity can be computed using *Quasi Monte Carlo* (QMC) methods as in (Genz and Bretz, 2009, Chapter 5.1).

3.4.1. Proof of Theorem 4

Fix a such that $0 \leq a \leq K-1$ and consider any selection procedure $\widehat{m}$ satisfying ($\mathscr{A}_{\text{Stop}}$). From Proposition 7, conditional on

$$\mathscr{F} := \left\{\widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K, \widehat{\imath}_{K+1} = i_{K+1}, \Lambda_a, \Lambda_{K+1}\right\}$$

and under the null hypothesis $\mathbb{H}_0 :$ "$X\beta^0 \in H_a$", we know that $m_{a+1} = \ldots = m_K = 0$. From Theorem 15 we know that the density of $(\Lambda_{a+1}, \Lambda_{a+2}, \ldots, \Lambda_K)$ conditional on $\mathscr{F}$ is given by

$$(const)\left[1 + \frac{1}{\nu}\sum_{k=a+1}^{K}\left(\frac{t_k}{\rho_k}\right)^2\right]^{-\frac{\nu+K-a}{2}} \mathbb{1}_{\Lambda_a \leq \ell_{a+1} \leq \cdots \leq \ell_K \leq \Lambda_{K+1}}.$$

From the definition of assumption ($\mathscr{A}_{\text{Stop}}$), and on the event $\mathscr{F}$, we know that the indicator $\mathbb{1}_{\{\widehat{m}=a\}}$ is a measurable function of $\lambda_1, \ldots, \lambda_{a-1}, \widehat{\sigma}_{\text{select}}$ which are respectively equal to $Z_{i_1}, \ldots, Z_{i_{a-1}}^{(i_1, \ldots, i_{a-2})}, \widehat{\sigma}_{\text{select}}^{i_1, \ldots, i_{K+1}}$ on $\mathscr{F}$ by (3.5) (as proven in Appendix A.3 and Eq. (A.3)). By Proposition 8 (more precisely (3.10)), we also know that this function is independent of $(\lambda_{a+1}, \lambda_{a+2}, \ldots, \lambda_K)$ conditional on $\mathscr{F}$. Remark that its is also independent of $\widehat{\sigma}_{\text{test}}^{i_1, \ldots, i_{K+1}}$ conditional on $\mathscr{F}$ for the same reason. We deduce that the conditional density above is also the conditional density on the event

$$\mathscr{G} := \left\{\widehat{m} = a, \widehat{\imath}_1 = i_1, \ldots, \widehat{\imath}_K = i_K, \widehat{\imath}_{K+1} = i_{K+1}, \Lambda_a, \Lambda_{K+1}\right\}.$$

Now, a simple integration shows that

$$\mathbb{P}\left[\Lambda_b \leq t \mid \widehat{m} = a, \Lambda_a, \Lambda_c, \widehat{\imath}_1, \ldots, \widehat{\imath}_{K+1}\right] = \frac{\widetilde{\mathbb{F}}_{abc}(t)}{\widetilde{\mathbb{F}}_{abc}(\Lambda_a)}. \qquad (3.25)$$

As a consequence and under the same conditioning, one has

$$\frac{\widetilde{\mathbb{F}}_{abc}(\Lambda_b)}{\widetilde{\mathbb{F}}_{abc}(\Lambda_a)} \sim \mathscr{U}(0,1).$$

Finally considerations of distribution under the alternative show that to obtain a p-value we must consider the complement to 1 of the quantity above.

3.4.2. t-Spacing tests and Generalized t-Spacing tests

One can consider the following testing procedures

$$\mathscr{T}_{abc} := \mathbb{1}_{\{\widehat{\beta}_{abc} \leq \alpha\}}, \tag{3.26}$$

that rejects if the p-value $\widehat{\beta}_{abc}$ is less than the level α of the test. This testing statistic generalizes previous testing statistics that appeared in t-Spacing Tests, as presented in Azaïs et al. (2018) for instance, and will be referred to as the *Generalized t-Spacing test* (GtSt).

Remark 15. *If one considers $a = 0$, $b = 1$ and $c = 2$ then one gets*

$$\widehat{\beta}_{012} = 1 - \frac{T_1(\Lambda_1) - T_1(\Lambda_2)}{T_1(\Lambda_0) - T_1(\Lambda_2)} = \frac{1 - T_1(\Lambda_1)}{1 - T_1(\Lambda_2)}.$$

Similarly, taking $b = a + 1$ and $c = a + 2$ one gets

$$\widehat{\beta}_{a(a+1)(a+2)} = \frac{T_{a+1}(\Lambda_{a+1}) - T_{a+1}(\Lambda_a)}{T_{a+1}(\Lambda_{a+2}) - T_{a+1}(\Lambda_a)}.$$

which is the t-spacing test as presented in Azaïs et al. (2018), where

$$T_k(\ell) := \int_{-\infty}^{\ell} \left[1 + \frac{1}{\nu}\left(\frac{\ell}{\rho_k}\right)^2 \right]^{-\frac{\nu+1}{2}} \mathrm{d}\ell \tag{3.27}$$

is, up to some positive numerical constant, the CDF of centered t-Student distribution with variance ρ_k^2 and $\nu = n_2$ degrees of freedom.

3.5. Power studies

3.5.1. Power when the design is orthogonal

One may investigate the power of these tests detecting false negatives, namely alternatives given by: there exists $k \in S^0$ such that $k \notin \{\bar{\iota}_1, \ldots, \bar{\iota}_a\}$. In particular, *what is the most powerful test among these latter* (1.4) *testing procedures?* A comprehensive study in the orthogonal case is given by Theorem 5.
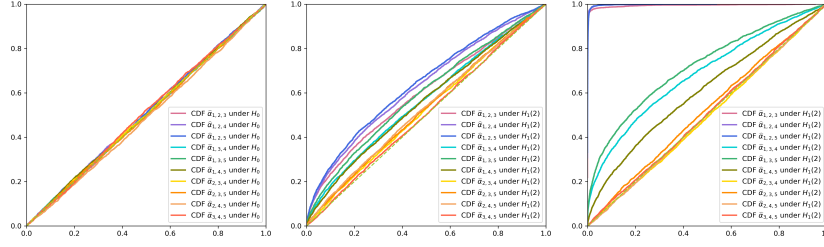

Figure 3: CDF of p-values $\widehat{\alpha}_{abc}$ over $3,000$ Monte-Carlo iterations and a random design $X \in \mathbb{R}^{n \times p}$ given by $p = 300$ independent column vectors uniformly distributed on the Euclidean sphere $\mathbb{S}^{199}$ ($n = 200$). Central panel represents alternative composed by 2-sparse vector, right panel alternative composed by 2-sparse vector 5 times larger while left panel corresponds to the null.

3.5.2. Numerical studies on power for the general design case

In the orthogonal design case, Theorem 5 shows that the test based on $\widehat{\alpha}_{a,a+1,K+1}$ is uniformly more powerful than tests based on $\widehat{\alpha}_{x,y,z}$ with $a \leq x < y < z \leq K + 1$. Numerical experiments on the power of these tests are presented in Figure 3 and they witness the same phenomenon for Gaussian designs. It presents the CDF of the p-value $\widehat{\alpha}_{abc}$ under the null and under two 2-sparse alternatives, one with low signal and one with 5 times more signal. Numerical results show that all the tests are exact (leftmost panel) and the test $\mathscr{S}_{125}$ is the most powerful. A detailed presentation of this experience is given in Section 4.2.

More precisely, it holds, as proved in the orthogonal case by Theorem 5 (and its proof), that

- $\widehat{\alpha}_{125} \preccurlyeq \widehat{\alpha}_{124} \preccurlyeq \widehat{\alpha}_{123}$;
- $\widehat{\alpha}_{125} \preccurlyeq \widehat{\alpha}_{135} \preccurlyeq \widehat{\alpha}_{235} \preccurlyeq \widehat{\alpha}_{234}$;
- $\widehat{\alpha}_{125} \preccurlyeq \widehat{\alpha}_{135} \preccurlyeq \widehat{\alpha}_{145} \preccurlyeq \widehat{\alpha}_{245}$.

where $\preccurlyeq$ denotes stochastic ordering. In the proof of Theorem 5 it is shown that

$$\widehat{\alpha}_{ab(c+1)} \preccurlyeq \widehat{\alpha}_{abc} \text{ and } \widehat{\alpha}_{a(b-1)c} \preccurlyeq \widehat{\alpha}_{abc} \text{ and } \widehat{\alpha}_{(a-1)bc} \preccurlyeq \widehat{\alpha}_{abc},$$

for orthogonal designs.

3.6. Control of False Discovery Rate in the Orthogonal Design case

3.6.1. Presentation in the general case

For sake of readability, we will assume, for the moment, that σ is known. We understand that the law of test statistics are parametrized by the hypotheses $(m_k)_{k \in [K]}$, where m_k is given by (3.12).

We recall that we denote $\overline{\mu}^0 = X^\top X \beta^0$ and $\overline{\mu}_i^0$ it ith coordinate. Assuming that predictors are normalised, in the general case, this quantity is the sum of β_i^0 and a

31

linear combination of the β_j^0's whose predictors X_j are highly correlated with the predictor X_i. Now, given variables $\bar{\iota}_1, \ldots, \bar{\iota}_k \in [p]$ and signs $\varepsilon_1, \ldots, \varepsilon_k \in \{\pm 1\}^k$, we denote by $(\Pi^\perp_{\bar{\iota}_1, \ldots, \bar{\iota}_{k-1}}(\overline{\mu}^0))_{\bar{\iota}_k}$ the orthogonal projection given by

$$(\Pi^\perp_{\bar{\iota}_1, \ldots, \bar{\iota}_{k-1}}(\overline{\mu}^0))_{\bar{\iota}_k} := \varepsilon_k X_{\bar{\iota}_k}^\top \Big[\mathrm{Id}_n - X_{\overline{S}^{k-1}} \big(X_{\overline{S}^{k-1}}^\top X_{\overline{S}^{k-1}} \big)^{-1} X_{\overline{S}^{k-1}}^\top \Big] X \beta^0. \tag{3.28}$$

The tested null hypotheses are conditional on some sub-sequence of variables $(\bar{\iota}_1, \ldots, \bar{\iota}_{K+1}) \in [p]^{K+1}$ and signs $\varepsilon_1, \ldots, \varepsilon_{K+1} \in \{\pm 1\}^{K+1}$ entering the model. The p-values under consideration are

- $\widehat{p}_1 := \widehat{\alpha}_{0,1,2}$ is the p-value testing $\mathbb{H}_{0,1}$: "$m_1 = 0$" namely $\overline{\mu}^0_{\bar{\iota}_1} = 0$;
- $\widehat{p}_2 := \widehat{\alpha}_{1,2,3}$ is the p-value testing $\mathbb{H}_{0,2}$: "$m_2 = 0$" namely $(\Pi^\perp_1(\overline{\mu}^0))_{\bar{\iota}_2} = 0$;
- $\widehat{p}_3 := \widehat{\alpha}_{2,3,4}$ is the p-value testing $\mathbb{H}_{0,3}$: "$m_3 = 0$" namely $(\Pi^\perp_2(\overline{\mu}^0))_{\bar{\iota}_3} = 0$;

$$\tag{3.29}$$

- and so on...

We write I_0 of the set

$$I_0 = \big\{ k \in [K] \ : \ \mathbb{H}_{0,k} \text{ is true} \big\},$$

Given a subset $\widehat{R} \subseteq [K]$ of hypotheses that we consider as rejected, we call *false positive* (FP) and *true positive* (TP) the quantities $\mathrm{FP} = \mathrm{card}(\widehat{R} \cap I_0)$ and $\mathrm{TP} = \mathrm{card}(\widehat{R} \setminus I_0)$.

Denote by $\widehat{p}_{(1)} \leq \ldots \leq \widehat{p}_{(K)}$ the p-values ranked in a nondecreasing order. Let $\alpha \in (0,1)$ and consider the Benjamini-Hochberg procedure, see for instance Benjamini and Hochberg (1995), defined by a rejection set $\widehat{R} \subseteq [K]$ such that $\widehat{R} = \emptyset$ when $\{k \in [K] \ : \ \widehat{p}_{(k)} \leq \alpha k / K\} = \emptyset$ and

$$\widehat{R} = \{ k \in [K] \ : \ \widehat{p}_k \leq \alpha \widehat{k}/K \} \quad \text{where} \quad \widehat{k} = \max \big\{ k \in [K] \ : \ \widehat{p}_{(k)} \leq \alpha k/K \big\}. \tag{3.30}$$

Recall the definition of FDR as the mean of False Discovery Proportion (FDP), namely

$$\mathrm{FDR} := \mathbb{E}\Big[\underbrace{\frac{\mathrm{FP}}{\mathrm{FP} + \mathrm{TP}} \mathbb{1}_{\mathrm{FP} + \mathrm{TP} \geq 1}}_{\mathrm{FDP}} \Big],$$

where the expectation is unconditional on the sequence of variables entering the model, while the hypotheses that are being tested are conditional on the sequence of variables entering the model. This FDR can be understood invoking the following decomposition

$$\mathrm{FDR} = \sum_{(\iota_1, \ldots, \iota_K) \in [p]^K} \overline{\pi}_{(\iota_1, \ldots, \iota_K)} \, \mathbb{E}\big[\mathrm{FDP} | \bar{\iota}_1 = i_1, \ldots, \bar{\iota}_K = i_K \big],$$

where $\overline{\pi}_{(\iota_1, \ldots, \iota_K)} = \mathbb{P}\big\{ \bar{\iota}_1 = \iota_1, \ldots, \bar{\iota}_K = \iota_K \big\}$.

3.6.2. FDR control of Benjamini–Hochberg procedure in the orthogonal design case

We now consider the orthogonal design case where $X^\top X = \mathrm{Id}_p$ and the set of p-values given by (3.29). Note that I_0 is simply the set of null coordinates of β. Remark also that, Irrepresentable Condition (Irrep.) of order p holds and so does Empirical Irrepresentable Check ($\mathscr{A}_{\mathrm{Irr.}}$), see Proposition 6.

Theorem 16. *Assume that the design is orthogonal, i.e. $X^\top X = \mathrm{Id}_p$, and let $K \in [p]$. Let $(\bar{\imath}_1, \ldots, \bar{\imath}_K)$ be the first variables entering along the LARS path. Consider the p-values given by (3.29) and the set $\widehat{R}$ given by (3.30). Then*

$$\mathbb{E}\big[\mathrm{FDP}|\bar{\imath}_1 = i_1, \ldots, \bar{\imath}_K = i_K\big] \leq \alpha,$$

and so FDR *is upper bounded by α.*

The proof of this result is given in Appendix C.7.

One interpretation *of post-selection type* may be given as follows: if one looks at all the experiments giving the same sequence of variables entering the model $\{\bar{\imath}_1 = i_1, \ldots, \bar{\imath}_K = i_K\}$ and if one considers the Benjamini–Hochberg procedure for the hypotheses described in Section 3.6.1, then the FDR is exactly controlled by α.

4. Admissible and testing procedures: numerical studies

4.1. Examples of admissible procedures

We present an admissible procedure to build an estimate $\widehat{S}$ of the support that satisfies ($\mathscr{A}_{\mathrm{Stop}}$). We chose a level $\alpha' \in (0,1)$ and we define a light modification of (3.26)

$$\mathscr{T}_{abc} = \mathbb{1}_{\{\widehat{\beta}_{abc} \leq \alpha'\}}, \tag{4.1}$$

by replacing the estimate $\widehat{\sigma}^2_{\mathrm{test}}$ by the estimate $\widehat{\sigma}^2_{\mathrm{select}}$. The number of degrees of freedom of the χ^2 distribution is now $\nu = n_1$. By a small abuse of notation, we still set

$$\Lambda_i := \frac{\lambda_i}{\widehat{\sigma}_{\mathrm{select}}}.$$

We limit our attention to consecutive $a, b, c \geq 0$. By Remark 15, one has

$$\widehat{\beta}_{a(a+1)(a+2)} = \frac{T_{a+1}(\Lambda_{a+1}) - T_{a+1}(\Lambda_a)}{T_{a+1}(\Lambda_{a+2}) - T_{a+1}(\Lambda_a)}.$$

which is the *t-spacing test* as presented in Azaïs et al. (2018), where the CDF T_{a+1} is defined by (3.27) with $\nu = n_1$ degrees of freedom. We are now in condition to present our algorithm.

- Begin with $a = 0$,
- at each step, perform the test $\mathscr{T}_{a,a+1,a+2}$ at the level α',
- if the test is significant, we set $a = a + 1$ and keep on going,
- if it is non-significant, we stop and set $\widehat{m} = a + 2$.

If the experimenter believes that there is no more than γ_{FP} consecutive false positives (FP) in the sequence of entries entering the model, then a less conservative admissible procedure would be the following:

- Begin with $a = 0$,
- at each step, perform the test $T_{a,a+1,a+2}$ at level α',
- if the test is significant, we set $a = a + 1$ and keep on going,
- if the γ_{FP} consecutive tests $T_{a,a+1,a+2}, T_{a+1,a+2,a+3}, \ldots, T_{a+\gamma_{FP}-1,a+\gamma_{FP},a+\gamma_{FP}+1}$ are all non-significants, we stop and set $\widehat{m} = a + \gamma_{FP} + 1$.

4.2. Power in the non-orthogonal case

To study the power in a *non-orthogonal* design case we have built a Monte-Carlo experiment with:

- a model with $n = 200$ observations and $p = 300$ predictors,
- a random design matrix X given by 300 independent column vectors uniformly distributed on the Euclidean sphere $\mathbb{S}^{199}$,
- and we ran $3,000$ Monte-Carlo experiments,
- the results are presented in Figure 3.

The computation of the function $\mathbb{F}_{abc}$ given by (3.19) requires multivariate integration tools. All our testing statistics can be efficiently computed using Quasi Monte Carlo methods (QMC) for Multi-Variate Normal (MVN) and t (MVT) distributions, see the book Genz and Bretz (2009) for a comprehensive treatment of this issue or Appendix D for a short overview of the method we used. We compute spacings of length at most 4 that implies $c \leq 5$ when $a = 1$ in our experimental framework.

A python notebook and codes are given at `https://github.com/ydecastro/lar_testing`. The base function is

```
observed_significance_CBC(lars, sigma, start, end, middle)
```

in the file `multiple_spacing_tests.py`. It gives the p-value $\widehat{\alpha}_{\texttt{(start)(middle)(end)}}$ of knots and indexes given by `lars` and an estimate of (or the true) standard deviation given by `sigma`. We have run $3,000$ repetitions of this function to get the laws displayed in Figure 3. It presents the CDF of the p-value $\widehat{\alpha}_{abc}$ under the null and under two 2-sparse alternatives, one with low signal and one with 5 times more signal. Results show, in our particular case, that all the tests are exact and the test $\mathscr{S}_{125}$ is the most powerful, see Section 3.5.2 for further details.

4.3. A comparison of FDR control and power on simulated data

We take the experiments introduced in (Javanmard et al., 2019, Section 5). As in this reference, we consider the linear model with a design X with independent rows draw with respect to $\mathcal{N}_p(0, \Sigma)$. The covariance $\Sigma \in \mathbb{R}^{p \times p}$ is such that $\Sigma_{ij} = r^{|i-j|}$, for some parameter $r \in (0,1)$. We then normalize the columns of X to have unit Euclidean norm. We draw a k-sparse vector $\beta^0 \in \mathbb{R}^p$ by choosing a support of size k

at random with values $\{\pm A\}$ uniformly at random, where $A > 0$ denotes the absolute value of the amplitudes. The Gaussian noise term η is drawn from $\mathcal{N}_n(0, \mathrm{Id}_n)$.

We compare the performances of three procedures:

- **[Knockoff]** Knockoff filters for FDR control (Barber et al., 2015) and we use the implementation presented on the webpage `https://web.stanford.edu/group/candes/knockoffs/`;
- **[FCD]** False Discovery Control via Debiasing (Javanmard et al., 2019, Section 5) and we use the implementation of debiased lasso presented on the webpage `https://web.stanford.edu/~montanar/sslasso/` with the theoretical value $\overline{\lambda} = 2\sqrt{(2\log p)/n}$ for the regularizing parameter;
- **[GtSt-BH]** Generalized t-Spacing tests on successive entries of the LARS path comibined with a Benjamini–Hochberg procedure Benjamini and Hochberg (1995) based on the sequence of spacings $\widehat{\beta}_{012}, \widehat{\beta}_{123}, \ldots, \widehat{\beta}_{a(a+1)(a+2)}, \ldots$ as described in Section 3.4 with nominal value $\alpha = 0.1$;

and we numerically investigate the effects of sparsity level, signal magnitude, feature correlation, and the empirical power. In all simulations, we set the target level FDR to $\alpha = 0.1$.

4.3.1. Effect of signal amplitude

We choose $n = 200$ (sample size), $p = 100$ (predictors), $k = 20$ (sparsity), $\eta = 0.1$ (features correlation) and vary the signal amplitude in the set $A \in [25]$. We compute the FDR and power by averaging across $3,000$ realizations of noise and the generation of coefficient vector β^0. The results are plotted in Figure 4.

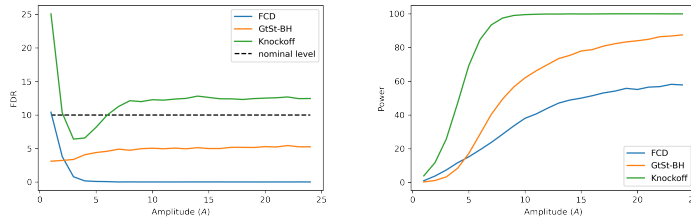

Figure 4: Comparison of the FDR control and power for GtSt, FCD and Knockoff when the signal amplitudes vary from 1 (low signal) to 25 (strong signal) over $3,000$ trials.

It appears that GtSt controls the FDR below the nominal value $\alpha = 0.1$ as FCD, while being more powerful than FCD (except for very low signal). Knockoff is the most powerful but it does not guarantee a FDR control below the nominal value.

35

4.3.2. Effect of feature correlation

We test the effect of feature correlations with $n = 200$, $p = 100$, $k = 20$, $A = 10$. Recall that the rows of the design matrix X are generated from a $\mathcal{N}_p(0, \Sigma)$ distribution, with $\Sigma_{ij} = \eta^{|i-j|}$, and then the columns of X are normalized to have unit norm. We vary the parameter η in the set $\{0.1, 0.15, 0.2, \ldots, 0.75, 0.8, 0.85\}$. For each value of η, we compute FDR and power, by averaging over $3,000$ realizations of noise and design matrix X. The results are displayed in Figure 5
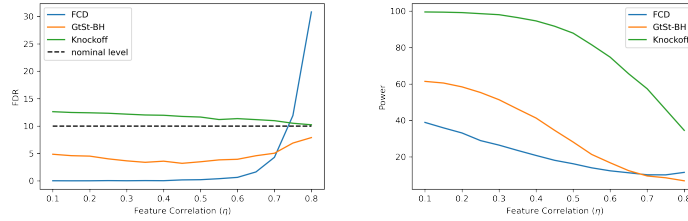

Figure 5: Comparison of the FDR control and power for GtSt, FCD and Knockoff when the feature correlation varies from 0.1 (low correlation) to 0.85 (strong correlation) over $3,000$ trials.

It appears that GtSt controls the FDR below the nominal value $\alpha = 0.1$ as FCD, while being more powerful than FCD. Knockoff is the most powerful but it does not guarantee a FDR control below the nominal value.

4.3.3. Effect of sparsity

We set $n = 200$, $p = 100$, $A = 10$, $\eta = 0.1$ and vary the sparsity level of the coefficients in the set $k \in [35]$. The power and FDR are computed by averaging over $3,000$ trials of noise and the generation of coefficient vector β^0.

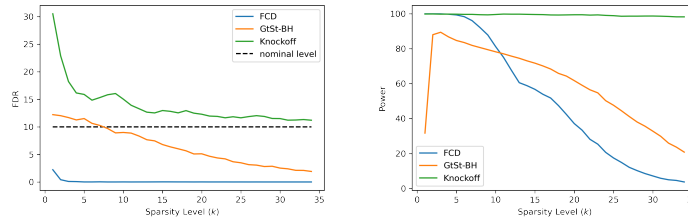

Figure 6: Comparison of the FDR control and power for GtSt, FCD and Knockoff when the feature correlation varies from 1 (very sparse) to 35 (slightly sparse) over $3,000$ trials.

It appears that GtSt controls the FDR below the nominal value $\alpha = 0.1$ as FCD, while being more powerful than FCD (except for very sparse signal). Knockoff is the most powerful but it does not guarantee a FDR control below the nominal value.

4.4. FDR on real data

A detailed presentation in a Python notebook is available at `https://github.com/ydecastro/lar_testing/blob/master/multiple_spacing_tests.ipynb`. We consider a data set about HIV drug resistance extracted from Barber et al. (2015) and Rhee et al. (2006). The experiment consists in identifying mutations on the genes of the HIV-virus that are involved with drug resistance. The data set contains about $p = 200$ and $n = 700$ observations. Since some protocol is used to remove some gene or some individuals, the exact numbers depend on the considered drug.

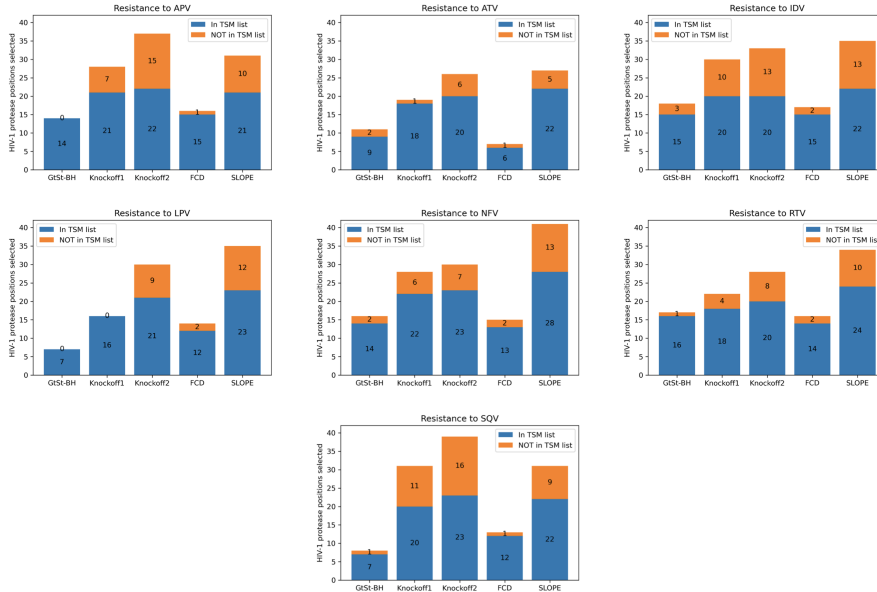

Figure 7: Comparison of the number of true and false positives for procedures: GtSt-BH, Knockoff (with SDP optimisation designs in Knockoff1 and equi-correlation designs in Knockoff2), FDC and Slope. In the procedures the aimed FDR is $\alpha = 20\%$. Blue color indicates protease positions that appear in the TSM panel for the PI class of treatments, given in (Rhee et al., 2006, Tabel 1), while orange indicates positions selected by the method that do not appear in the TSM list. The total number of HIV-1 protease positions appearing in the TSM list is 34.

The methods considered are **[Knockoff]**, **[FCD]**, **[GtSt-BH]**, and:

- **[Slope]** Slope for FDR control, as presented in the paper (Bogdan et al., 2015).

The comparison is displayed in Figure 7. It appears that GtSt-BH and FCD procedures are more conservative but they give a better control of the False Discovery Proportion (FDP). Slope and Knockoff are more powerful at the price of FDP greater than the expected FDR $\alpha = 0.2$ (in at least 4 experiments out of 7). Knockoff1 presents a better FDP than Slope.

Supplement to
Multiple Testing and Variable Selection along Least Angle Regression's path

Appendix A: Representing the LARS knots

A.1. The equivalent formulations of the LARS algorithm

We present here three equivalent formulations of the LARS that are a consequence of the analysis provided in Appendices A and B. One formulation is given by Algorithm 1.

Algorithm 3: LARS algorithm (standard formulation)

Data: Correlations vector $\overline{Z}$ and variance-covariance matrix $\overline{R}$.
Result: Sequence $((\lambda_k, \bar{\imath}_k, \varepsilon_k))_{k \geq 1}$ where $\lambda_1 \geq \lambda_2 \geq \ldots > 0$ are the knots, and $\bar{\imath}_1, \bar{\imath}_2, \ldots$ are the variables that enter the model with signs $\varepsilon_1, \varepsilon_2, \ldots$ ($\varepsilon_k = \pm 1$).

```
/* Initialize computing (λ₁,ī₁,ε₁) and defining a "residual" N̄⁽¹⁾.        */
```
1 Set $k = 1$, $\lambda_1 := \max |\overline{Z}|$, $\bar{\imath}_1 := \arg\max |\overline{Z}|$ and $\varepsilon_1 = \overline{Z}_{\bar{\imath}_1} / \lambda_1 \in \pm 1$, and $\overline{N}^{(1)} := \overline{Z}$.

```
/* Note that ((λ_ℓ,ī_ℓ,ε_ℓ))_{1≤ℓ≤k-1} and N̄⁽ᵏ⁻¹⁾ have been defined at the previous
   step.                                                                  */
```
2 Set $k \leftarrow k + 1$ and compute the least-squares fit

$$\overline{\theta}_j := \left(\overline{R}_{j,\bar{\imath}_1} \cdots \overline{R}_{j,\bar{\imath}_{k-1}} \right) M_{\bar{\imath}_1, \ldots, \bar{\imath}_{k-1}}^{-1} (\varepsilon_1, \ldots, \varepsilon_{k-1}), \quad j = 1, \ldots, p,$$

where $M_{\bar{\imath}_1, \ldots, \bar{\imath}_{k-1}}$ is the sub-matrix of $\overline{R}$ keeping the columns and the rows indexed by $\{\bar{\imath}_1, \ldots, \bar{\imath}_{k-1}\}$.

3 For $0 < \lambda \leq \lambda_{k-1}$ compute the "residuals" $\overline{N}^{(k)}(\lambda) = (\overline{N}_1^{(k)}(\lambda), \ldots, \overline{N}_p^{(k)}(\lambda))$ given by

$$\overline{N}_j^{(k)}(\lambda) := \overline{N}_j^{(k-1)} - (\lambda_{k-1} - \lambda)\overline{\theta}_j, \quad j = 1, \ldots, p,$$

and pick

$$\lambda_k := \max \left\{ \beta > 0 \,;\, \exists j \notin \{\bar{\imath}_1, \ldots, \bar{\imath}_{k-1}\}, \text{ s.t. } |\overline{N}_j^{(k)}(\beta)| = \beta \right\} \text{ and } \bar{\imath}_k := \underset{j \notin \{\bar{\imath}_1, \ldots, \bar{\imath}_{k-1}\}}{\arg\max} |\overline{N}_j^{(k)}(\lambda_k)|,$$

$$\varepsilon_k := \overline{N}_{\bar{\imath}_k}^{(k)}(\lambda_k)/\lambda_k \in \pm 1 \text{ and } \overline{N}^{(k)} := \overline{N}^{(k)}(\lambda_k).$$

Then, iterate from **2**.

Algorithm 4: LARS algorithm ("projected" formulation)

Data: Correlations vector $\overline{Z}$ and variance-covariance matrix $\overline{R}$.

Result: Sequence $((\lambda_k, \overline{\iota}_k, \varepsilon_k))_{k \geq 1}$ where $\lambda_1 \geq \lambda_2 \geq \ldots > 0$ are the knots, and $\overline{\iota}_1, \overline{\iota}_2, \ldots$ are the variables that enter the model with signs $\varepsilon_1, \varepsilon_2, \ldots$ ($\varepsilon_k = \pm 1$).

```
/* Initialize computing (λ₁, ῑ₁, ε₁).                                    */
```

1 Define $Z = (\overline{Z}, -\overline{Z})$ and R as in (2.4), and set $k = 1$, $\lambda_1 := \max Z$, $\widehat{\iota}_1 := \arg\max Z$, $\overline{\iota}_1 = \widehat{\iota}_1$ mod p and $\varepsilon_1 = 1 - 2(\widehat{\iota}_1 - \overline{\iota}_1)/p \in \pm 1$.

```
/* Note that ((λₗ,ῑₗ))₁≤ₗ≤ₖ₋₁ have been defined at the previous step/loop.  */
```

2 Set $k \leftarrow k + 1$ and compute

$$\lambda_k = \max_{\{j\,:\,\theta_j(\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}) < 1\}} \left\{ \frac{Z_j - \Pi_{\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}}(Z_j)}{1 - \theta_j(\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1})} \right\} \quad \text{and} \quad \widehat{\iota}_k = \arg\max_{\{j\,:\,\theta_j(\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}) < 1\}} \left\{ \frac{Z_j - \Pi_{\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}}(Z_j)}{1 - \theta_j(\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1})} \right\},$$

where

$$\Pi_{\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}}(Z_j) := \left(R_{j,\widehat{\iota}_1} \cdots R_{j,\widehat{\iota}_{k-1}} \right) M_{\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}}^{-1} (Z_{\widehat{\iota}_1}, \ldots, Z_{\widehat{\iota}_{k-1}})$$

$$\theta_j(\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}) := \left(R_{j,\widehat{\iota}_1} \cdots R_{j,\widehat{\iota}_{k-1}} \right) M_{\widehat{\iota}_1,\ldots,\widehat{\iota}_{k-1}}^{-1} (1, \ldots, 1)$$

and set $\overline{\iota}_k = \widehat{\iota}_k$ mod p and $\varepsilon_k = 1 - 2(\widehat{\iota}_k - \overline{\iota}_k)/p \in \pm 1$. Then, iterate from **2**.

A.2. Initialization: First Knot

The first step of the LARS algorithm (Step **1** in Algorithm 3) seeks the most correlated predictor with the observation. In our formulation, introduce the first residual $N^{(1)} := Z$ and observe that $N^{(1)} := (\overline{N}^{(1)}, -\overline{N}^{(1)})$. We define the first knot $\lambda_1 > 0$ as

$$\lambda_1 = \max Z \quad \text{and} \quad \widehat{\iota}_1 = \arg\max Z.$$

One may see that this definition is consistent with λ_1 in Algorithm 3 and note that $\widehat{\iota}_1$ and $(\overline{\iota}_1, \varepsilon_1)$ are related as in (2.1).

The LARS algorithm is a forward algorithm that selects a new variable and maintains a residual at each step. We also define

$$N^{(2)}(\lambda) = N^{(1)} - (\lambda_1 - \lambda)\theta(\widehat{\iota}_1), \quad 0 < \lambda \leq \lambda_1, \tag{A.1}$$

and one can check that $N^{(2)}(\lambda) = (\overline{N}^{(2)}(\lambda), -\overline{N}^{(2)}(\lambda))$ where $\overline{N}(\lambda)$ is defined in Algorithm 3. It is clear that the coordinate $\widehat{\iota}_1$ of $N^{(2)}(\lambda)$ is equal to λ. On the other hand $N^{(1)} = Z$ attains its maximum at the single point $\widehat{\iota}_1$. By continuity this last property is kept for λ in a left neighborhood of λ_1. We search for the first value of λ such that this property is not met, *i.e.* the largest value of λ such that

$$\exists j \neq \widehat{\iota}_1 \text{ such that } N^{(2)}(\lambda) = \lambda,$$

as in Step **3** of Algorithm 3. We call this value λ_2 and one may check that this definition is consistent with λ_2 in Algorithm 3.

Now, we can be more explicit about the expression of λ_2. Indeed, we make the following discussion on the values of $\theta_j(\widehat{\iota}_1)$.

42

- If $\theta_j(\widehat{\imath}_1) \geq 1$, since $N_j^{(1)} < N_{\widehat{\imath}_1}^{(1)}$ for $j \neq \widehat{\imath}_1$ there is no hope to achieve the equality between $N_j^{(2)}(\lambda)$ and $N_{\widehat{\imath}_1}^{(2)}(\lambda) = \lambda$ for $0 < \lambda \leq \lambda_1$ in view of (A.1).
- Thus we limit our attention to the j's such that $\theta_j(\widehat{\imath}_1) < 1$. We have equality $N_j^{(2)}(\lambda) = \lambda$ when

$$\lambda = \frac{N_j^{(1)} - \lambda_1 \theta_j(\widehat{\imath}_1)}{1 - \theta_j(\widehat{\imath}_1)}.$$

So we can also define the second knot λ_2 of the LARS as

$$\lambda_2 = \max_{j:\theta_j(\widehat{\imath}_1)<1} \left\{ \frac{Z_j - \Pi_{\widehat{\imath}_1}(Z_j)}{1 - \theta_j(\widehat{\imath}_1)} \right\}.$$

where $\Pi_{i_1}(Z_j) := Z_{i_1}\theta_j(i_1)$. Remark that $\Pi_{i_1}(Z_j) = \mathbb{E}(Z_j \mid Z_{i_1})$ is the regression of Z_j on Z_{i_1} when $\mathbb{E}Z = 0$.

A.3. Recursion: Next Knots

The loop ($\mathbf{2} \rightleftarrows \mathbf{3}$) in Algorithm 3 builds iteratively the knots $\lambda_1, \lambda_2 \ldots$ of the LARS algorithm and some "residuals" $\overline{N}^{(1)}, \overline{N}^{(2)}, \ldots$ defined in Step $\mathbf{3}$. We will present here an equivalent formulation of these knots.

Assume that $k \geq 2$ and we have build $\lambda_1, \ldots, \lambda_{k-1}$ and selected the "signed" variables $\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}$. Introduce $N^{(k-1)} := (\overline{N}^{(k-1)}, -\overline{N}^{(k-1)})$ and define

$$N^{(k)}(\lambda) = N^{(k-1)} - (\lambda_{k-1} - \lambda)\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}), \quad 0 < \lambda \leq \lambda_{k-1}.$$

Check that $\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}) = (\overline{\theta}_j, -\overline{\theta}_j)$ where we recall that we define

$$\overline{\theta}_j := \left(\overline{R}_{j,\bar{\imath}_1} \cdots \overline{R}_{j,\bar{\imath}_{k-1}} \right) M_{\bar{\imath}_1,\ldots,\bar{\imath}_{k-1}}^{-1} (\varepsilon_1, \ldots, \varepsilon_{k-1}), \quad j = 1, \ldots, p,$$

at Step $\mathbf{2}$ and it holds that $\widehat{\imath}_\ell$ and $(\bar{\imath}_\ell, \varepsilon_\ell)$ are related as in (2.1). From this equality, we deduce that it holds $N^{(k)}(\lambda) = (\overline{N}^{(k)}(\lambda), -\overline{N}^{(k)}(\lambda))$. One may also check that the coordinates $\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}$ of $N^{(k)}(\lambda)$ are equal to λ.

Again if we want to solve $N_j^{(k)}(\lambda) = \lambda$ for some j, we have to limit our attention to j's such that $\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}) < 1$. Solving this latter equality yields to

$$\lambda_k = \max_{j:\theta_j(\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1})<1} \left\{ \frac{N_j^{(k-1)} - \lambda_{k-1}\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1})}{1 - \theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1})} \right\}.$$

This expression is consistent with λ_k in Algorithm 3.

Now, we can give an other expression of λ_k that will be useful in the proofs of our main theorems. Note that the residuals satisfy the relation

$$N^{(k)} = N^{(k-1)} - (\lambda_{k-1} - \lambda_k)\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}), \tag{A.2}$$

and that $N_j^{(k-1)} = \lambda_{k-1}$ for $j = \widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}$. The following lemma permits a drastic simplification of the expression of the knots. Its proof is given in Appendix C.5.

43

Lemma 17. *It holds*

$$N^{(k-1)} - \lambda_{k-1}\theta(\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1}) = Z - \Pi_{\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1}}(Z)$$

where we denote $\Pi_{i_1,\dots,i_{k-1}}(Z) = (\Pi_{i_1,\dots,i_{k-1}}(Z_1),\dots,\Pi_{i_1,\dots,i_{k-1}}(Z_{2p}))$ *and for all* $j \in [2p]$
one has $\Pi_{i_1,\dots,i_{k-1}}(Z_j) = \left(R_{j,i_1}\cdots R_{j,i_{k-1}}\right)M^{-1}_{i_1,\dots,i_{k-1}}(Z_{i_1},\dots,Z_{i_{k-1}}).$

Using Lemma 17 we deduce that λ_k in Algorithm 3 is consistent with

$$\lambda_k = \max_{j:\theta_j(\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1})<1}\left\{\frac{Z_j - \Pi_{\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1}}(Z_j)}{1 - \theta_j(\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1})}\right\}. \tag{A.3}$$

where $\Pi_{\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1}}(Z_j) = \left(R_{j,\widehat{\imath}_1}\cdots R_{j,\widehat{\imath}_{k-1}}\right)M^{-1}_{\widehat{\imath}_1,\dots,\widehat{\imath}_{k-1}}(Z_{\widehat{\imath}_1},\dots,Z_{\widehat{\imath}_{k-1}}).$ When $\mathbb{E}Z = 0$, one
may remark that $\Pi_{i_1,\dots,i_{k-1}}(Z_j)$ is the regression of Z_j on the vector $(Z_{i_1},\cdots,Z_{i_{k-1}})$
whose variance-covariance matrix is $M_{i_1,\dots,i_{k-1}}$. This analysis leads to an equivalent
formulation of the LARS algorithm (Algorithm 3). We present this formulation in
Algorithm 4.

Remark 16. *Note that Algorithm 3 implies that* $\widehat{\imath}_1,\dots,\widehat{\imath}_k$ *are pairwise different, but
also that they differ modulo* p.

Appendix B: First Steps to Derive the Joint Law of the LARS knots

B.1. *Law of the First Knot*

One has the following lemma governing the law of λ_1.

Lemma 18. *It holds that*

- Z_{i_1} *is independent of* $(Z_j^{(i_1)})_{j\neq i_1}$,
- *If* $\theta_j(i_1) < 1$ *for all* $j \neq i_1$ *then*

$$\left\{\widehat{\imath}_1 = i_1\right\} = \left\{\lambda_2^{(i_1)} \leq Z_{i_1}\right\},$$

- *If* $\theta_j(i_1) < 1$ *for all* $j \neq i_1$ *then, conditional on* $\{\widehat{\imath}_1 = i_1\}$ *and* λ_2, λ_1 *is a truncated
  Gaussian random variable with mean* $\mathbb{E}(Z_{i_1})$ *and variance* $\rho_1^2 := R_{\widehat{\imath}_1,\widehat{\imath}_1}$ *subject
  to be greater than* λ_2.

Proof. The first point is a consequence or the properties of Gaussian regression.
Now, observe that

$$\left\{\lambda_2^{(i_1)} \leq Z_{i_1}\right\} \Longleftrightarrow \left\{\forall j \neq i_1,\ \frac{Z_j - Z_{i_1}\theta_j(i_1)}{1 - \theta_j(i_1)} \leq Z_{i_1}\right\}$$

$$\Longleftrightarrow \left\{\forall j \neq i_1,\ Z_j - Z_{i_1}\theta_j(i_1) \leq Z_{i_1} - Z_{i_1}\theta_j(i_1)\right\}$$

$$\Longleftrightarrow \left\{\forall j \neq i_1,\ Z_j \leq Z_{i_1}\right\}$$

$$\Longleftrightarrow \left\{\widehat{\imath}_1 = i_1\right\},$$

as claimed. The last statement is a consequence of the two previous points. □

44

B.2. Recursive Formulation of the LARS

One has the following proposition whose proof can be found in Section C.6. As we will see in this section, this intermediate result as a deep consequence, the LARS algorithm can be stated in a recursive way applying the same function repeatedly, as presented in Algorithm 1.

Proposition 19. *Set*

$$\tau_{j,i_k} := \frac{R_{j,i_k} - \left(R_{j,i_1} \cdots R_{j,i_{k-1}}\right) M_{i_1,\ldots,i_{k-1}}^{-1} \left(R_{i_k,i_1}, \cdots, R_{i_k,i_{k-1}}\right)}{(1 - \theta_j(i_1,\ldots,i_{k-1}))(1 - \theta_{i_k}(i_1,\ldots,i_{k-1}))},$$

and observe that τ_{j,i_k} is the covariance between $Z_j^{(i_1,\ldots,i_{k-1})}$ and $Z_{i_k}^{(i_1,\ldots,i_{k-1})}$. Furthermore, it holds

$$\frac{\tau_{j,i_k}}{\tau_{i_k,i_k}} = 1 - \frac{1 - \theta_j(i_1,\ldots,i_k)}{1 - \theta_j(i_1,\ldots,i_{k-1})} \tag{B.1}$$

and

$$\forall j \neq i_1,\ldots,i_k, \quad Z_j^{(i_1,\ldots,i_k)} = \frac{Z_j^{(i_1,\ldots,i_{k-1})} - Z_{i_k}^{(i_1,\ldots,i_{k-1})} \tau_{j,i_k}/\tau_{i_k,i_k}}{1 - \tau_{j,i_k}/\tau_{i_k,i_k}}. \tag{B.2}$$

Now, we present Algorithm 1. Define $R(0) := R$, $Z(0) = Z$ and $T(0) = 0$. For $k \geq 1$ and fixed $i_1,\ldots,i_k \in [2p]$, introduce

$$R(k) := \left(R_{j,\ell} - \left(R_{j,i_1} \cdots R_{j,i_k}\right) M_{i_1,\ldots,i_k}^{-1} \left(R_{\ell,i_1}, \cdots, R_{\ell,i_k}\right)\right)_{j,\ell}$$

$$Z(k) := Z - \Pi_{i_1,\ldots,i_k}(Z)$$

$$T(k) := (\theta_j(i_1,\ldots,i_k))_j,$$

and note that $R(k)$ is the variance-covariance matrix of the Gaussian vector $Z(k)$. The key property is following. Let $v_1,\ldots,v_k$, be k linearly independent vectors of an Euclidean space and let u be any vector of the space. Set

$$v := P_{(v_1,\ldots,v_{k-1})}^{\perp} v_k,$$

the projection of v_k orthogonally to $v_1,\ldots,v_{k-1}$. Then

$$P_{(v_1,\ldots,v_k)}^{\perp} u = P_v^{\perp} P_{(v_1,\ldots,v_{k-1})}^{\perp} u.$$

Using this result we deduce that

$$\begin{aligned}
Z(k) &= \Pi_{i_1,\ldots,i_k}^{\perp}(Z) \\
&= \Pi_{i_k}^{\perp}(\Pi_{i_1,\ldots,i_{k-1}}^{\perp}(Z)) \\
&= \Pi_{i_k}^{\perp}(Z(k-1)) \\
&= Z(k-1) - \Pi_{i_k}(Z(k-1)) \\
&= Z(k-1) - \mathbf{x}(k)Z(k-1),
\end{aligned} \tag{B.3}$$

45

where $\mathbf{x}(k) = R_{i_k}(k-1)/R_{i_k,i_k}(k-1)$. It yields that

$$R(k) = R(k-1) - \mathbf{x}(k)R_{i_k}(k-1)^\top. \tag{B.4}$$

Using (B.1) (or (C.9)), remark that

$$T(k) = T(k-1) - \mathbf{x}(k)(1 - T_{i_k}(k-1)). \tag{B.5}$$

These relations give a recursive formulation of the LARS as presented in Algorithm 1.

Appendix C: Proofs

C.1. *Proof of Proposition 8*

The proof of the first point can be lead by induction. The initialization of the proof is given by the first point of Lemma 18. Now, observe that $Z_{i_k}^{(i_1,\ldots,i_{k-1})}, \cdots, Z_{i_2}^{(i_1)}, Z_{i_1}$ are measurable functions of $(Z_{i_1}, \ldots, Z_{i_k})$ and one may check that $(Z_{i_1}, \ldots, Z_{i_k})$ is independent of $(Z_{i_{k+1}}^{(i_1,\ldots,i_k)}, (Z_j^{(i_1,\ldots,i_{k+1})})_{j \neq i_1,\ldots,i_{k+1}})$. We deduce that $Z_{i_k}^{(i_1,\ldots,i_{k-1})}, \cdots, Z_{i_2}^{(i_1)}, Z_{i_1}$ are independent of $(Z_{i_{k+1}}^{(i_1,\ldots,i_k)}, (Z_j^{(i_1,\ldots,i_{k+1})})_{j \neq i_1,\ldots,i_{k+1}})$. One can also check that $Z_{i_{k+1}}^{(i_1,\ldots,i_k)}$ is independent of $(Z_j^{(i_1,\ldots,i_{k+1})})_{j \neq i_1,\ldots,i_{k+1}}$. We know also that they are independent of $P_{K+1}^\perp Y$ leading to their independence of the estimates of the standard error given by (2.13). These two estimates are independent since they are built on orthogonal Gaussian vectors.

The second point also works by induction. The initialization of the proof is given by the second point of Lemma 18. We will use Proposition 19 to prove the second point.

Now, we have

$$
\begin{aligned}
&\lambda_{k+1}^{(i_1,\ldots,i_k)} \leq Z_{i_k}^{(i_1,\ldots,i_{k-1})} \\
&\Leftrightarrow \forall j \neq i_1,\ldots,i_k, \ Z_j^{(i_1,\ldots,i_k)} \leq Z_{i_k}^{(i_1,\ldots,i_{k-1})} \\
&\Leftrightarrow \forall j \neq i_1,\ldots,i_k, \ Z_j^{(i_1,\ldots,i_{k-1})} - Z_{i_k}^{(i_1,\ldots,i_{k-1})} \frac{\tau_{j,i_k}}{\tau_{i_k,i_k}} \leq Z_{i_k}^{(i_1,\ldots,i_{k-1})} - Z_{i_k}^{(i_1,\ldots,i_{k-1})} \frac{\tau_{j,i_k}}{\tau_{i_k,i_k}} \\
&\Leftrightarrow \forall j \neq i_1,\ldots,i_k, \ Z_j^{(i_1,\ldots,i_{k-1})} \leq Z_{i_k}^{(i_1,\ldots,i_{k-1})} \hspace{2.5cm} \text{(C.1)} \\
&\Leftrightarrow \lambda_k^{(i_1,\ldots,i_{k-1})} = Z_{i_k}^{(i_1,\ldots,i_{k-1})}.
\end{aligned}
$$

using that (B.2) and that $1 - \tau_{j,i_k}/\tau_{i_k,i_k} > 0$ (which is a consequence of (B.1)

46

and $(\mathcal{A}_{\mathrm{Irr.}})$ in (C.1). By induction and using (C.1), it holds that

$$\left\{\lambda_{k+1}^{(i_1,\dots,i_k)} \le Z_{i_k}^{(i_1,\dots,i_{k-1})} \le Z_{i_{k-1}}^{(i_1,\dots,i_{k-2})} \le \dots \le Z_{i_2}^{(i_1)} \le Z_{i_1}\right\}$$

$$\Leftrightarrow \left\{\forall j \ne i_1,\dots,i_k,\ Z_j^{(i_1,\dots,i_{k-1})} \le Z_{i_k}^{(i_1,\dots,i_{k-1})} \le Z_{i_{k-1}}^{(i_1,\dots,i_{k-2})} \le \dots \le Z_{i_2}^{(i_1)} \le Z_{i_1}\right\}$$

$$\Leftrightarrow \left\{\forall j \ne i_1,\dots,i_{k-1},\ Z_j^{(i_1,\dots,i_{k-1})} \le Z_{i_{k-1}}^{(i_1,\dots,i_{k-2})} \le \dots \le Z_{i_2}^{(i_1)} \le Z_{i_1}\right.$$

$$\left.\text{and } \forall j \ne i_1,\dots,i_k,\ Z_j^{(i_1,\dots,i_{k-1})} \le Z_{i_k}^{(i_1,\dots,i_{k-1})}\right\}$$

$$\Leftrightarrow \left\{\lambda_k^{(i_1,\dots,i_{k-1})} \le Z_{i_{k-1}}^{(i_1,\dots,i_{k-2})} \le \dots \le Z_{i_2}^{(i_1)} \le Z_{i_1} \text{ and } \lambda_k^{(i_1,\dots,i_{k-1})} = Z_{i_k}^{(i_1,\dots,i_{k-1})}\right\}$$

$$\vdots$$

$$\Leftrightarrow \left\{\lambda_a^{(i_1,\dots,i_{a-1})} \le Z_{i_{a-1}}^{(i_1,\dots,i_{a-2})} \le \dots \le Z_{i_2}^{(i_1)} \le Z_{i_1}\right.$$

$$\left.\text{and } \lambda_k^{(i_1,\dots,i_{k-1})} = Z_{i_k}^{(i_1,\dots,i_{k-1})} \le \dots \le \lambda_a^{(i_1,\dots,i_{a-1})} = Z_{i_a}^{(i_1,\dots,i_{a-1})}\right\} \qquad (s_a)$$

$$\vdots$$

$$\Leftrightarrow \left\{\widehat{\iota}_1 = i_1,\dots,\widehat{\iota}_k = i_k\right\}.$$

Now, observe that $\widehat{\iota}_{k+1}$ is the (unique) arg max of $\lambda_{k+1}^{(i_1,\dots,i_k)}$ on the event $\{\widehat{\iota}_1 = i_1,\dots,\widehat{\iota}_k = i_k\}$. It yields that

$$\left\{\widehat{\iota}_1 = i_1,\dots,\widehat{\iota}_{k+1} = i_{k+1}\right\} \ = \left\{\lambda_{k+1}^{(i_1,\dots,i_k)} = Z_{i_{k+1}}^{(i_1,\cdots,i_k)} \le Z_{i_k}^{(i_1,\cdots,i_{k-1})} \le \cdots \le Z_{i_2}^{(i_1)} \le Z_{i_1}\right\},$$

as claimed. Stopping at a as in (s_a) gives the second part of the statement.

C.2. Proof of Proposition 10

Fix a such that $0 \le a \le K-1$ and consider any selection procedure $\widehat{m}$ satisfying $(\mathcal{A}_{\mathrm{Stop}})$. From Theorem 2 (more precisely (3.15)) we know that the density of $(\lambda_{a+1}, \lambda_{a+2}, \dots, \lambda_K)$ conditional on

$$\mathcal{F} := \left\{\widehat{\iota}_1 = i_1,\dots,\widehat{\iota}_K = i_K, \widehat{\iota}_{K+1} = i_{K+1}, \lambda_a, \lambda_{K+1}\right\}$$

is given by

$$(const)\left(\prod_{k=a+1}^{K} \varphi_{m_k, v_k^2}(\ell_k)\right) \mathbb{1}_{\lambda_a \le \ell_{a+1} \le \cdots \le \ell_K \le \lambda_{K+1}}.$$

From Proposition 7, conditional on $\mathcal{F}$ and under the null hypothesis of Proposition 10, we know that $m_{a+1} = \dots = m_K = 0$. It implies that Φ_k is the CDF of λ_k for $a < k \le K$.

From definition $(\mathcal{A}_{\mathrm{Stop}})$ and on the event $\mathcal{F}$, we know that $\mathbb{1}_{\{\widehat{m}=a\}}$ is a measurable function of $\lambda_1,\dots,\lambda_{a-1}, \widehat{\sigma}_{\mathrm{select}}$ which are respectively equal to $Z_{i_1},\dots,Z_{i_{a-1}}^{(i_1,\dots,i_{a-2})}, \widehat{\sigma}_{\mathrm{select}}^{i_1,\dots,i_{K+1}}$ on $\mathcal{F}$ by (3.5) (as proven in Appendix A.3 and Eq. (A.3)). By Proposition 8 (more precisely (3.10)), we also know that this function is independent of $(\lambda_{a+1}, \lambda_{a+2}, \dots, \lambda_K)$ conditional on $\mathcal{F}$. Remark that its is also independent of $\widehat{\sigma}_{\mathrm{test}}^{i_1,\dots,i_{K+1}}$ conditional of $\mathcal{F}$
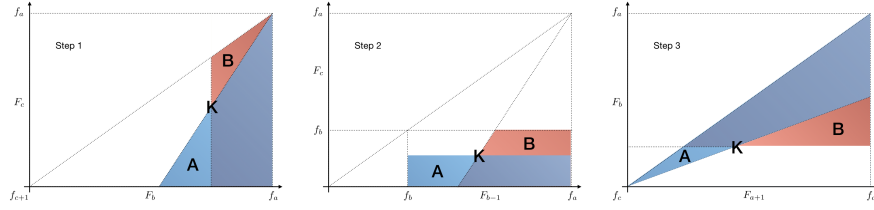

Figure 8: Rejection domains associated to the different comparison sets appearing in steps of the proof of Theorem 5.

for the same reason (it would be useful later, when we will build testing procedures when the variance is unknown). We deduce that the conditional density above is also the conditional density on the event

$$\mathcal{G} := \left\{ \widehat{m} = a, \widehat{\iota}_1 = i_1, \ldots, \widehat{\iota}_K = i_K, \widehat{\iota}_{K+1} = i_{K+1}, \lambda_a, \lambda_{K+1} \right\}.$$

From $F_k = \Phi_k(\lambda_k)$ (*i.e.*, applying the CDF) we deduce by a change of variables that conditional on the selection event $\mathcal{G}$, the vector $(F_{a+1}, \ldots, F_K)$ is uniformly distributed on

$$\mathcal{D}_{a+1,K} := \Big\{ (f_{a+1}, \ldots, f_K) \in \mathbb{R}^{K-a} :$$
$$\mathcal{P}_{a+1,a}(F_a) \geq f_{a+1} \geq \mathcal{P}_{a+1,a+2}(f_{a+2}) \geq \cdots \geq \mathcal{P}_{a+1,K}(f_K) \geq \mathcal{P}_{a+1,K+1}(F_{K+1}) \Big\},$$

where $\mathcal{P}_{i,j}$ are described in (3.16).

C.3. Proof of Proposition 11

By Proposition 10, a simple integration shows that

$$\mathbb{P}\Big[\lambda_b \leq t \mid \widehat{m} = a, \lambda_a, \lambda_c, \widehat{\iota}_1, \ldots, \widehat{\iota}_a, \widehat{\iota}_{a+1}, \ldots, \widehat{\iota}_{c-1}, \widehat{\iota}_c, \ldots, \widehat{\iota}_{K+1} \Big] = \frac{\mathbb{F}_{abc}(t)}{\mathbb{F}_{abc}(\lambda_a)},$$

under the null hypothesis of Proposition 11 (which implies that $m_{a+1} = \ldots = m_K = 0$). Then note that the function $\mathbb{F}_{abc}$ is defined by $\sigma, \lambda_a, \lambda_c, \widehat{\iota}_{a+1}, \ldots, \widehat{\iota}_{c-1}$ only. We deduce that we can de-condition on $\widehat{m} = a, \widehat{\iota}_1, \ldots, \widehat{\iota}_a, \widehat{\iota}_c, \ldots, \widehat{\iota}_{K+1}$, which gives the result.

C.4. Orthogonal Case: Proof of Theorem 5

Let $\mathcal{I}$ the set of admissible indexes

$$\mathcal{I} := \{ a, b, c : a_0 \leq a < b < c \leq K+1 \}.$$

∘ **Step 1:** We prove that, when the considered indexes such that $c + 1 \leq K + 1$ belong to $\mathcal{I}$, $\mathcal{S}_{a,b,c+1}$ is more powerful than $\mathcal{S}_{a,b,c}$. Our proof is conditional to $F_a =$

48

$f_a, F_{c+1} = f_{c+1}$. Note that $(F_{a+1}, \ldots, F_c)$ has for distribution the uniform distribution on the simplex

$$\mathcal{S} := \{f_a > F_{a+1} > \cdots > F_c > f_{c+1}\}.$$

This implies by direct calculations that

$$\mathcal{I}_{ab}(s, t) = \frac{(s-t)^{b-a-1}}{(b-a-1)!}$$

and that

$$\frac{\mathbb{F}_{abc}(\lambda_b)}{\mathbb{F}_{abc}(\lambda_a)} = \boldsymbol{F}_{\beta((b-a),(c-b))}\left(\frac{F_b - F_c}{f_a - F_c}\right). \tag{C.2}$$

where $\boldsymbol{F}_\beta$ is the cumulative distribution of the Beta distribution in reference. Using monotony of this function the $\mathcal{S}_{abc}$ test has for rejection region

$$(F_b - F_c) \geq z_1(f_a - F_c) \Longleftrightarrow F_b \geq z_1 f_a + (1 - z_1)F_c, \tag{C.3}$$

where z_1 is some threshold, depending on α, that belongs to $(0, 1)$.

Similarly $\mathcal{S}_{ab(c+1)}$ has for rejection region

$$F_b \geq z_2(f_a - f_{c+1}) + f_{c+1}, \tag{C.4}$$

where z_2 is some other threshold belonging to $(0, 1)$. We use the following lemmas.

Lemma 20. *Let $c \leq K$. The density h_μ of $f_1, \ldots, f_c$, conditional on F_{c+1} with respect of the Lebesgue measure under the alternative is coordinate-wise non-decreasing and given by* (C.5).

Proof. Observe that it suffises to prove the result when $\sigma = 1$. Note that

$$\lambda_{c+1}^{i_1,\ldots,i_c} = \max_{j \in [p], \; j \neq \bar{i}_1, \ldots, j \neq \bar{i}_c} |Z_j|.$$

Thus its density $p_{\mu^0, i_1, \ldots, i_c}$ does not depend on $\mu_{\bar{i}_1}^0, \ldots, \mu_{\bar{i}_c}^0$. As a consequence the following variables have the same distribution ; $\lambda_{c+1}^{i_1 + \epsilon_1 p, \ldots, i_c + \epsilon_c p}$, where $\epsilon_1, \ldots, \epsilon_c$ take the value 0 or 1 and indices are taken modulo p.

Because of independence of the different variables, the joint density, under the alternative, of $\lambda_1, \ldots, \lambda_{c+1}$ taken at $\ell_1, \ldots, \ell_{c+1}$, on the domain $\{\lambda_1 > \cdots > \lambda_{c+1}\}$ takes the value

$$(Const) \sum{}' \left(\varphi(\ell_1 - \mu_{j_1}^0) + \varphi(\ell_1 + \mu_{j_1}^0)\right), \ldots, \left(\varphi(\ell_c - \mu_{j_c}^0) + \varphi(\ell_c + \mu_{j_c}^0)\right) p_{\mu^0, j_1, \ldots, j_K}(\ell_{k+1}).$$

Here the sum $\sum{}'$ is taken over all different $j_1, \ldots, j_c$ belonging to $[\![1, p]\!]$.

Then the density, conditional on $F_{c+1} = f_{c+1}$, of $F_1, \ldots, F_c$ at $f_1, \ldots, f_c$ takes the value

$$(\mathrm{const}) \sum{}' \cosh(\mu_{j_1} f_1) \ldots \cosh(\mu_{j_c} f_c) \mathbb{1}_{f_1 > \cdots > f_c > F_{c+1}}, \tag{C.5}$$

implying that this density is coordinate-wise non-decreasing. $\square$

Lemma 21. *Let ν_0 the image on the plane (F_b, F_c) on the uniform probability on $\mathscr{S}$: it is the distribution under the null of (F_b, F_c). The two rejection regions : $\mathscr{R}_1$ associated to (C.3) and $\mathscr{R}_2$ associated to (C.4) have of course the same probability α under ν_0. Let η_{μ^0} the density w.r.t. ν_0 of the distribution of (F_b, F_c) under the alternative.*

Then η_{μ^0} is non decreasing coordinate-wise.

Proof. Integration yields that density of ν_0 w.r.t. the Lebesgue measure taken at point (f_b, f_c) is

$$\frac{(f_a - f_b)^{b-a-1}(f_b - f_c)^{c-b-1}}{(b-a-1)!(c-b-1)!}.$$

The density of ν_{μ^0} w.r.t. Lebesgue measure is

$$\int_{f_b}^{f_a} df_{a+1} \dots \int_{f_b}^{f_b-2} df_{a+1} \int_{f_b}^{f_b-2} df_{b-1} \int_{f_c}^{f_b} df_{b+1} \dots \int_{f_c}^{f_c-2} df_{c-1} h_{\mu^0}(f_a, \dots, f_c).$$

(C.6)

Thus η_{μ^0} which is the quotient of these two quantities is just a mean value of h_{μ^0} on the domain of integration $\mathscr{D}_{f_b, f_c}$ in (C.6).

Suppose that f_b and f_c increase, then all the borns of the domain $\mathscr{D}_{f_b, f_c}$ increase also. By Lemma 20 the mean value increases. □

We finish now the proof of Step 1: For a given level α let us consider the two rejection regions $R_{a,b,c}$ and $R_{a,b,(c+1)}$ of the two considered tests in the plane F_b, F_c and set

$$A := R_{a,b,c} \setminus R_{a,b,(c+1)} \text{ and } B := R_{a,b,(c+1)} \setminus R_{a,b,c},$$

see Figure 8. These two regions have the same ν_0 measure. By elementary geometry there exist a point $K = (K_b, K_c)$ in the plane such that

- For every point of A, $F_b \leq K_b$, $F_c \leq K_c$,
- For every point of B, $F_b \geq K_b$, $F_c \geq K_c$,

By transport of measure there exists a transport function $\mathscr{T}$ that preserve the measure ν_0 and that is one-to one $A \to B$. As a consequence the transport by $\mathscr{T}$ improve the probability under the alternative: the power of $\mathscr{S}_{a,b,c+1}$ is larger than that of $\mathscr{S}_{a,b,c}$.

○ **Step 2:** We prove that, when the considered indexes belong to $\mathscr{I}$ such that $a < b - 1$, $\mathscr{S}_{a,(b-1),c}$ is more powerful than $\mathscr{S}_{a,b,c}$. Our proof is conditional on $F_a = f_a, F_b = f_b$ and is located in the plane (F_{b-1}, F_c).

The rejection region $R_{a,b,c}$ takes the form $F_c \leq \frac{1}{1-z_1} f_b - \frac{z_1}{1-z_1} f_a$ for some threshold z_1 belonging to $(0, 1)$.

The rejection region $R_{a,(b-1),c}$ takes the form $F_c \leq \frac{1}{1-z_2} F_{b-1} - \frac{z_2}{1-z_2} f_a$ for some other threshold z_2 belonging to $(0, 1)$.

These regions as well as the regions A and B and the point K are indicated in Figure 8.

Transport of measure and the convenient modification of Lemma 21 imply that the power of $\mathscr{S}_{a,(b-1),c}$ is greater of equal that that of $\mathscr{S}_{a,b,c}$.

50

∘ **Step 3:** We prove that, when the considered indexes belong to $\mathscr{I}$ such that $a+1 < b$, $\mathscr{S}_{a,b,c}$ is more powerful than $\mathscr{S}_{(a+1),b,c}$. Our proof is conditional on $F_a = f_a, F_c = f_c$ and is located in the plane F_{a+1}, F_b.

The rejection region $R_{a,b,c}$ takes the form $F_b \geq z_1 f_a + (1-z_1)f_c$ for some threshold z_1 belonging to $(0,1)$.

The rejection region $R_{a+1,b,c}$ takes the form $F_b \geq z_2 F_{a+1} + (1-z_2)f_c$ for some other threshold z_2 belonging to $(0,1)$.

These regions as well as the regions A and B and the point K are indicated in Figure 8.

Transport of measure and the convenient modification of Lemma 21 imply that the power of $\mathscr{S}_{a,b,c}$ is greater of equal that that of $\mathscr{S}_{(a+1),b,c}$.

Considering the three cases above, we get the desired result.

C.5. *Proof of Lemma* 17

The proof works by induction. Let us check the relation for $k = 2$, namely

$$N^{(1)} - \lambda_1 \theta(\widehat{\imath}_1) = Z - Z_{\widehat{\imath}_1}\theta(\widehat{\imath}_1) = Z - \Pi_{\widehat{\imath}_1}(Z).$$

Now, let $k \geq 3$. First, the three perpendicular theorem implies that for every $j, i_1, \ldots, i_{k-1}$,

$$\theta_j(i_1, \ldots, i_{k-2}) = \left(R_{j,i_1} \cdots R_{j,i_{k-1}}\right)M_{i_1,\ldots,i_{k-1}}^{-1}(\theta_{i_1}(i_1, \ldots, i_{k-2}), \ldots, \theta_{i_{k-1}}(i_1, \ldots, i_{k-2})),$$

and $\Pi_{i_1,\ldots,i_{k-2}}(Z_j) = \left(R_{j,i_1} \cdots R_{j,i_{k-1}}\right)M_{i_1,\ldots,i_{k-1}}^{-1}(\Pi_{i_1,\ldots,i_{k-2}}(Z_{i_1}), \ldots, \Pi_{i_1,\ldots,i_{k-2}}(Z_{i_{k-1}}))$.

By induction, using (A.2), we get that

$$
\begin{aligned}
N^{(k-1)} &= N^{(k-2)} - (\lambda_{k-2} - \lambda_{k-1})\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2}), \\
&= (N^{(k-2)} - \lambda_{k-2}\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2})) + \lambda_{k-1}\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2}), \\
&= Z - \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z) + \lambda_{k-1}\theta(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2}). \quad\quad (C.7)
\end{aligned}
$$

Then, recall that $N_j^{(k-1)} = \lambda_{k-1}$ for $j = \widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}$ and remark that

$$\lambda_{k-1}\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}) = \left(R_{j,\widehat{\imath}_1} \cdots R_{j,\widehat{\imath}_{k-1}}\right)M_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}^{-1}(N_{\widehat{\imath}_1}^{(k-1)}, \ldots, N_{\widehat{\imath}_{k-1}}^{(k-1)}).$$

Using (C.7) at indices $j = \widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}$, we deduce that

$$
\begin{aligned}
&\lambda_{k-1}\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-1}) \\
&= \left(R_{j,\widehat{\imath}_1} \cdots R_{j,\widehat{\imath}_{k-1}}\right)M_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}^{-1}(N_{\widehat{\imath}_1}^{(k-1)}, \ldots, N_{\widehat{\imath}_{k-1}}^{(k-1)}) \\
&= \left(R_{j,\widehat{\imath}_1} \cdots R_{j,\widehat{\imath}_{k-1}}\right)M_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}^{-1}(Z_{\widehat{\imath}_1}, \ldots, Z_{\widehat{\imath}_{k-1}}) \\
&\quad - \left(R_{j,\widehat{\imath}_1} \cdots R_{j,\widehat{\imath}_{k-1}}\right)M_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}^{-1}(\Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z_{\widehat{\imath}_1}), \ldots, \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z_{\widehat{\imath}_{k-1}})) \\
&\quad + \lambda_{k-1}\left(R_{j,\widehat{\imath}_1} \cdots R_{j,\widehat{\imath}_{k-1}}\right)M_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}^{-1}(\theta_{\widehat{\imath}_1}(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2}), \ldots, \theta_{\widehat{\imath}_{k-1}}(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2})) \\
&= \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}(Z_j) - \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z_j) + \lambda_{k-1}\theta_j(\widehat{\imath}_1, \ldots, \widehat{\imath}_{k-2}),
\end{aligned}
$$

51

Namely

$$\Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}(Z) - \lambda_{k-1}\theta(\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}) = \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z) - \lambda_{k-1}\theta(\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}).$$

Using again (C.7) we get that

$$\begin{aligned}
N^{(k-1)} &= Z - \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}}(Z) + \lambda_{k-1}\theta(\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-2}), \\
&= Z - \Pi_{\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}}(Z) + \lambda_{k-1}\theta(\widehat{\imath}_1,\ldots,\widehat{\imath}_{k-1}),
\end{aligned}$$

as claimed.

C.6. Proof of Proposition 19

We denote

$$\begin{aligned}
R_j &:= \left(R_{j,i_1},\ldots,R_{j,i_{k-1}}\right), \\
R_{i_k} &:= \left(R_{i_k,i_1},\ldots,R_{i_k,i_{k-1}}\right), \\
M &:= M_{i_1,\ldots,i_{k-1}}, \\
\overline{M} &:= M_{i_1,\ldots,i_k} = \begin{bmatrix} M & R_{i_k} \\ R_{i_k}^\top & R_{i_k,i_k} \end{bmatrix}, \\
\overline{R} &:= \left(R_{j,i_1},\ldots,R_{j,i_k}\right), \\
x &:= \frac{1 - \theta_j(i_1,\ldots,i_{k-1})}{1 - \theta_{i_k}(i_1,\ldots,i_{k-1})}\frac{\tau_{j,i_k}}{\tau_{i_k,i_k}},
\end{aligned}$$

and observe that

$$x = \frac{R_{j,i_k} - R_j^\top M^{-1} R_{i_k}}{R_{i_k,i_k} - R_{i_k}^\top M^{-1} R_{i_k}},$$

$$\overline{M}^{-1} = \begin{bmatrix} \mathrm{Id}_{k-1} & -M^{-1}R_{i_k} \\ 0 & 1 \end{bmatrix}\begin{bmatrix} M^{-1} & 0 \\ 0 & \left(R_{i_k,i_k} - R_{i_k}^\top M^{-1} R_{i_k}\right)^{-1} \end{bmatrix}\begin{bmatrix} \mathrm{Id}_{k-1} & 0 \\ -R_{i_k}^\top M^{-1} & 1 \end{bmatrix},$$

$$\overline{M}^{-1}\overline{R} = \begin{bmatrix} M^{-1}\left(R_j - xR_{i_k}\right) \\ x \end{bmatrix}, \tag{C.8}$$

using Schur complement of block M of the matrix $\overline{M}$ and a LU decomposition. Note also that

$$\frac{Z_j^{(i_1,\ldots,i_{k-1})} - Z_{i_k}^{(i_1,\ldots,i_{k-1})}\tau_{j,i_k}/\tau_{i_k,i_k}}{1 - \tau_{j,i_k}/\tau_{i_k,i_k}} = \frac{Z_j - \Pi_{i_1,\ldots,i_{k-1}}(Z_j) - x\left(Z_{i_k} - \Pi_{i_1,\ldots,i_{k-1}}(Z_{i_k})\right)}{1 - \theta_j(i_1,\ldots,i_{k-1}) - x(1 - \theta_{i_k}(i_1,\ldots,i_{k-1}))}.$$

To prove (B.2), it suffices to show that the R.H.S term above is equal to the following R.H.S term

$$Z_j^{(i_1,\ldots,i_k)} = \frac{Z_j - \Pi_{i_1,\ldots,i_k}(Z_j)}{1 - \theta_j(i_1,\ldots,i_k)}.$$

We will prove that numerators are equal and that denominators are equal. For denominators,

$$1 - \theta_j(i_1, \ldots, i_{k-1}) - x(1 - \theta_{i_k}(i_1, \ldots, i_{k-1}))$$
$$= 1 - \theta_j(i_1, \ldots, i_{k-1}) - x + x\,\theta_{i_k}(i_1, \ldots, i_{k-1})$$
$$= 1 - \underbrace{(1 \cdots 1)}_{k \text{ times}} \begin{bmatrix} M^{-1}(R_j - xR_{i_k}) \\ x \end{bmatrix}$$
$$= 1 - \theta_j(i_1, \ldots, i_k), \tag{C.9}$$

using (C.8). Furthermore, it proves (B.1). For the numerators, we use that

$$Z_j - \Pi_{i_1,\ldots,i_{k-1}}(Z_j) - x\,(Z_{i_k} - \Pi_{i_1,\ldots,i_{k-1}}(Z_{i_k}))$$
$$= Z_j - \Pi_{i_1,\ldots,i_{k-1}}(Z_j) - xZ_{i_k} + x\Pi_{i_1,\ldots,i_{k-1}}(Z_{i_k})$$
$$= Z_j - (Z_{i_1} \cdots Z_{i_k}) \begin{bmatrix} M^{-1}(R_j - xR_{i_k}) \\ x \end{bmatrix}$$
$$= Z_j - \Pi_{i_1,\ldots,i_k}(Z_j).$$

using (C.8).

C.7. *Proof of Theorem 16*

We rely on the **Weak Positive Regression Dependency (WPRDS) property** to prove the result, one may consult (Giraud, 2014, Page 173) for instance. We say that a function $g : [0,1]^K \to \mathbb{R}^+$ is *nondecreasing* if for any $p, q \in [0,1]^K$ such that $p_k \geq q_k$ for every $k = 1, \ldots, K$, we have $g(p) \geq g(q)$. We say that a Borel set $\Gamma \in [0,1]^K$ is *nondecreasing* if $g = \mathbb{1}_\Gamma$ is nondecreasing. In other words if $y \in \gamma$ and if $z \geq 0$, then $y + z \in \gamma$. We say that the p-values $(\widehat{p}_1 = \widehat{\alpha}_{0,1,K+1}, \ldots, \widehat{p}_K = \widehat{\alpha}_{K-1,K,K+1})$ satisfy the WPRDS property if for any nondecreasing set Γ and for all $k^0 \in I_0$, the function

$$u \mapsto \mathbb{P}_{\mu^0}\big[(\widehat{p}_1, \ldots, \widehat{p}_K) \in \Gamma \big| \widehat{p}_{k^0} \leq u \big] \text{ is nondecreasing}$$

where $\mu^0 = \beta^0$ in our orthogonal design case, and we recall that

$$I_0 = \big\{ k \in [K] \ : \ \mathbb{H}_{0,k} \text{ is true} \big\}.$$

To prove Theorem 16, note that it is sufficient (Giraud, 2014, Chapter 8) to prove that

$$u \mapsto \overline{\mathbb{P}}\big[(\widehat{p}_1, \ldots, \widehat{p}_K) \in \Gamma \big| \widehat{p}_{k^0} \leq u \big] \text{ is nondecreasing} \tag{C.10}$$

where $\overline{\mathbb{E}}, \overline{\mathbb{P}}$ will denote that expectations and probabilities are conditional on $\{\bar{\imath}_1, \ldots, \bar{\imath}_K, \lambda_{K+1}\}$ and under the hypothesis that $\mu^0 = X^\top X \beta^0$. Note that one can integrate in λ_{K+1} to get the statement of Theorem 16.

○ **Step 1:** We start by giving the joint law of the LARS knots under the alternative in the orthogonal design case. Lemma 20 and (C.5) show that, conditional

53

on $\{\bar{\imath}_1,\ldots,\bar{\imath}_K,\lambda_{K+1}\}$, $(\lambda_1,\ldots,\lambda_K)$ is distributed on the set $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_K \geq \lambda_{K+1}$ and it has a coordinate-wise nondecreasing density. Now we can assume without loss of generality that $\sigma^2 = 1$, in addition because of orthogonality $\rho_k^2 = 1$ implying that $F_k = \Phi(\lambda_k)$ $\mathscr{P}_{i,j} = \Phi_i \circ \Phi_j^{-1} = \mathrm{Id}$. We deduce that, conditional on $\{\bar{\imath}_1,\ldots,\bar{\imath}_K,F_{K+1}\}$, $(F_1,\ldots,F_K)$ is distributed on the set

$$\big\{(f_1,\ldots,f_K) \in \mathbb{R}^K \ : \ 1 \geq f_1 \geq f_2 \geq \cdots \geq f_K \geq F_{K+1})\big\},$$

it has an **explicit density** given by (C.5), and we denote it by h_{μ^0}. By the change of variables $G_k := \frac{F_k - F_{K+1}}{F_{k-1} - F_{K+1}}$ one obtains that the distribution of $(G_1,\ldots,G_K)$ is supported on $[0,1]^K$. More precisely, define

$$\psi(f_1,\ldots,f_K) := (g_1,\ldots,g_K) := \big(\frac{f_1 - F_{K+1}}{1 - F_{K+1}}, \ldots, \frac{f_K - F_{K+1}}{f_{K-1} - F_{K+1}}\big)$$

$$\psi^{-1}(g_1,\ldots,g_K) := \Big((1 - F_{K+1})g_1 + F_{K+1}, \ldots, (1 - F_{K+1})g_1 g_2 \ldots g_K + F_{K+1}\Big),$$

whose inverse Jacobian determinant is

$$\det\Big[\frac{\partial \psi}{\partial f_1} \cdots \frac{\partial \psi}{\partial f_K}\Big]^{-1} = \prod_{k=1}^{K}(f_{k-1} - F_{K+1}) = (1 - F_{K+1})^K \prod_{k=1}^{K} g_k^{K-k}.$$

We deduce that the density of $(G_1,\ldots,G_K)|\{\bar{\imath}_1,\ldots,\bar{\imath}_K,F_{K+1}\}$ at point g with respect to Lebesgue measure is

$$\mathbf{p}(g) := (\mathrm{const})\mathbb{1}_{g \in (0,1)^K} \prod_{k=1}^{K} g_k^{K-k} \cosh\Big[\mu_{i_k}^0\big((1 - F_{K+1})\prod_{\ell=1}^{k} g_\ell + F_{K+1}\big)\Big], \quad \text{(C.11)}$$

where we have used (C.5). From (1.3) and (C.2), one has

$$\widehat{p}_k = 1 - \boldsymbol{F}_{\beta(1,K-k+1)}\Big(\frac{F_k - F_{K+1}}{F_{k-1} - F_{K+1}}\Big) = 1 - \boldsymbol{F}_{\beta(1,K-k+1)}(G_k) \quad \text{(C.12)}$$

where $\boldsymbol{F}_\beta$ is the cumulative distribution of the Beta distribution in reference. We deduce that for any $v \in (0,1)$ and for any $\ell \in [K]$,

$$\widehat{p}_k = v \Longleftrightarrow (G_1,\ldots,G_K) \in [0,1]^K \cap \{\boldsymbol{F}_{\beta(1,K-k+1)}^{-1}(1-v) = G_k\},$$

so that

$$\mathbb{P}\big[(\widehat{p}_1,\ldots,\widehat{p}_K) \in \Gamma \big| \widehat{p}_{k^0} \leq u\big] = \overline{\mathbb{P}}\big[(G_1,\ldots,G_K) \in \overline{\Gamma} \big| G_{k^0} \geq \boldsymbol{F}_{\beta(1,K-\ell+1)}^{-1}(1-u)\big], \quad \text{(C.13)}$$

where $\overline{\Gamma}$ can be proved to be a **nonincreasing Borel set** from (C.12).

∘ **Step 2:** Let $0 < x < y < 1$ and denote by μ_x the following conditional law

$$\mu_x := \mathrm{law}\big[(G_1,\ldots,G_K)|\{\bar{\imath}_1,\ldots,\bar{\imath}_K,F_{K+1},G_{k^0} \geq x\}\big].$$

Remark that if there exists a measurable $T : [0,1]^K \mapsto [0,1]^K$ such that

54

- T is nondecreasing, meaning that for any $g \in [0,1]^K$, $T(g) \geq g$;
- T is such that push-forward of μ_x by T gives μ_y, namely $T_\# \mu_x = \mu_y$;

then it holds

- $\mathbb{1}_{\{T(g) \in \bar{\Gamma}\}} \leq \mathbb{1}_{\{g \in \bar{\Gamma}\}}$;
- $\text{law}\big[T(G) | \{\bar{\imath}_1, \dots, \bar{\imath}_K, F_{K+1}, G_{k^0} \geq x\} \big] = \text{law}\big[G | \{\bar{\imath}_1, \dots, \bar{\imath}_K, F_{K+1}, G_{k^0} \geq y\} \big]$
  where $G = (G_1, \dots, G_K)$.

In this case, we deduce that

$$\overline{\mathbb{P}}\big[G \in \bar{\Gamma} \big| G_{k^0} \geq x \big] \geq \overline{\mathbb{P}}\big[T(G) \in \bar{\Gamma} \big| G_{k^0} \geq x \big] = \overline{\mathbb{P}}\big[G \in \bar{\Gamma} \big| G_{k^0} \geq y \big].$$

If one can prove that such function T exists for any $0 < x < y < 1$, it proves that

$$x \mapsto \overline{\mathbb{P}}\big[G \in \bar{\Gamma} \big| G_{k^0} \geq x \big] \text{ is nonincreasing},$$

and, in view of (C.13), it proves (C.10). Proving that such function T exists is done in the next step.

○ **Step 3:** Let $0 < x < y < 1$. Consider the **Knothe-Rosenblatt transport map** T of μ_x toward μ_y following the order

$$k^0 \to k^0 + 1 \to \cdots \to K \to k^0 - 1 \to k^0 - 2 \to \cdots \to 1.$$

It is based on a sequence of conditional quantile transforms defined following the ordering above. Its construction is presented for instance in (Santambrogio, 2015, Sec.2.3, P.67) or (Villani, 2008, P.20). The transport T is defined as follows. Given $z, z' \in [0,1]^K$ such that $z' = T(z)$ it holds

$$z'_{k^0} = T^{(k^0)}(z_{k^0});$$
$$z'_{k^0+1} = T^{(k^0+1)}(z_{k^0+1}, z'_{k^0});$$
$$\vdots$$
$$z'_K = T^{(K)}(z_K, z'_{K-1}, \dots, z'_{k^0});$$
$$z'_{k^0-1} = T^{(k^0-1)}(z_{k^0-1}, z'_K, \dots, z'_{k^0});$$
$$\vdots$$
$$z'_1 = T^{(1)}(z_1, z'_2, \dots, z'_{k^0-1}, z'_K, \dots, z'_{k^0});$$

where $T^{(k^0)}, T^{(k^0+1)}, \dots, T^{(K)}, T^{(k^0-1)} \dots, T^{(1)}$ will be build in the sequel, in which we will drop their dependencies in the z'_k's to ease notations. It remains to prove that

- T is nondecreasing, meaning that for any $g \in [0,1]^K$, $T(g) \geq g$;
- T is such that push-forward of μ_x by T gives μ_y, namely $T_\# \mu_x = \mu_y$;

to conclude. The last point is a property of the Knothe-Rosenblatt transport map. Proving the first point will be done in the rest of the proof.

○ *Step 3.1:* We start by the first transport map $T^{(k^0)} : [0,1] \mapsto [0,1]$. Denote $\mu_x^{(k^0)}$ the following conditional law

$$\mu_x^{(k^0)} := \text{law}\big[G_{k^0} | \{\bar{\imath}_1, \dots, \bar{\imath}_K, F_{K+1}, G_{k^0} \geq x\}\big],$$

and $\mathbb{F}_x^{(k^0)}$ its cdf. Note that the Knothe-Rosenblatt construction gives $T^{(k^0)} = (\mathbb{F}_y^{(k^0)})^{-1} \circ \mathbb{F}_x^{(k^0)}$. We would like to prove that $T^{(k^0)}(t) \geq t$ for all $z \in (0,1)$. This is equivalent to prove that it holds $\mathbb{F}_x^{(k^0)} \geq \mathbb{F}_y^{(k^0)}$. For $t \leq y$, $\mathbb{F}_y^{(k^0)}(t) = 0$ and it implies that $\mathbb{F}_x^{(k^0)}(t) \geq \mathbb{F}_y^{(k^0)}(t)$. Let $t > y$, using the conditional density $\mathbf{p}$ defined in (C.11), note that

$$\mathbb{F}_x^{(k^0)}(t) \geq \mathbb{F}_y^{(k^0)}(t) \quad \Longleftrightarrow \quad \frac{\int_x^t \mathbf{p}}{\int_x^1 \mathbf{p}} \geq \frac{\int_y^t \mathbf{p}}{\int_y^1 \mathbf{p}}$$

$$\Longleftrightarrow \quad \int_x^t \int_y^1 \mathbf{p} \otimes \mathbf{p} \geq \int_y^t \int_x^1 \mathbf{p} \otimes \mathbf{p},$$

where, for example

$$\int_x^t \quad \text{means the integral over the hyper rectangle } [x,t] := \Big\{(g_1, \dots, g_K) \in [0,1]^K : x \leq g_{k^0} \leq t\Big\}.$$

A simple calculation (see also Figure 9) gives that

$$\int_x^t \int_y^1 \mathbf{p} \otimes \mathbf{p} = \int_y^t \int_x^1 \mathbf{p} \otimes \mathbf{p} + \int_{[x,y] \times [t,1]} \mathbf{p} \otimes \mathbf{p},$$

and it proves that $\mathbb{F}_x^{(k^0)} \geq \mathbb{F}_y^{(k^0)}$.

○ *Step 3.2:* We continue with the second transport map in Knothe-Rosenblatt construction. Let $z_{k^0} \in (x,1)$ and denote $\mu_{z_{k^0}}^{(k^0+1)}$ the following conditional law

$$\mu_{z_{k^0}}^{(k^0+1)} := \text{law}\big[G_{k^0+1} | \{\bar{\imath}_1, \dots, \bar{\imath}_K, F_{K+1}, G_{k^0} = z_{k^0}\}\big],$$

and $\mathbb{F}_{z_{k^0}}^{(k^0+1)}$ its cdf. Let $z'_{k^0} := T^{(k^0)}(z'_{k^0})$ and denote $\mu_{z'_{k^0}}^{(k^0+1)}$ the following conditional law

$$\mu_{z'_{k^0}}^{(k^0+1)} := \text{law}\big[G_{k^0+1} | \{\bar{\imath}_1, \dots, \bar{\imath}_K, F_{K+1}, G_{k^0} = z'_{k^0}\}\big],$$

and $\mathbb{F}_{z'_{k^0}}^{(k^0+1)}$ its cdf. Note that $x < z_{k^0} \leq z'_{k^0} = T^{(k^0)}(z_{k^0}) \leq 1$. Again, we would like to prove that $\mathbb{F}_{z_{k^0}}^{(k^0+1)} \geq \mathbb{F}_{z'_{k^0}}^{(k^0+1)}$ which implies that the transport map $T^{(k^0+1)} := \big(\mathbb{F}_{z'_{k^0}}^{(k^0+1)}\big)^{-1} \circ \mathbb{F}_{z_{k^0}}^{(k^0+1)}$ satisfies $T^{(k^0+1)}(u) \geq u$ for all $u \in (0,1)$.
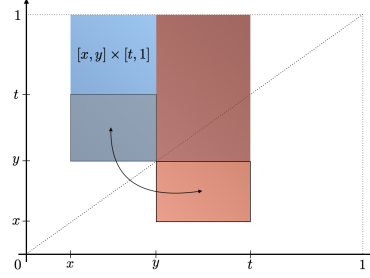

56

Figure 9: Note that, by symmetry the two boxed regions have same $\mathbf{p} \otimes \mathbf{p}$ measure. The blue region is $[x, t] \times [y, 1]$, its measure is the measure of the red region (namely $c D_y(t) \times \mathscr{D}_x(1)$) more the bluest upper left corner (namely $[x, y] \times [t, 1]$).

Recall that the conditional density $\mathbf{p}$ of $G|\{\bar{\iota}_1, \ldots, \bar{\iota}_K, F_{K+1}\}$ is given by (C.11) and recall that $k^0 \in I_0$. Observe that $\mu_{k^0}^0 = 0$, so that the conditional density of $G|\{\bar{\iota}_1, \ldots, \bar{\iota}_K, F_{K+1}, G_{k^0} = \mathbf{z}\}$ is

$$(\text{const}) \, \mathbb{1}_{g \in (0,1)^K} \mathbb{1}_{g_{k^0} = \mathbf{z}} \prod_{k < k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \prod_{\ell=1}^{k} g_\ell + F_{K+1})\Big] \qquad (\text{C.14})$$
$$\times \prod_{k > k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \, \mathbf{z} \prod_{1 \le \ell \ne k^0 \le k} g_\ell + F_{K+1})\Big].$$

Set $\tau := z'_{k^0}/z_{k^0} \ge 1$ and $G'_{k^0+1} = \tau G_{k^0+1}$ so that

$$z_{k^0} G_{k^0+1} = z'_{k^0} G'_{k^0+1}.$$

Denote $G' := (G_1, \ldots, G_{k^0-1}, G'_{k^0+1}, G_{k^0+2}, \ldots, G_K) \in (0, 1)^{k^0-1} \times (0, \tau) \times (0, 1)^{K-k^0-1}$ and note that the conditional density of $G'|\{\bar{\iota}_1, \ldots, \bar{\iota}_K, F_{K+1}, G_{k^0} = \tau \mathbf{z}\}$ is

$$(\text{const}) \, \mathbb{1}_{g \in (0,1)^{k^0-1} \times (0,\tau) \times (0,1)^{K-k^0-1}} \prod_{k < k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \prod_{\ell=1}^{k} g_\ell + F_{K+1})\Big]$$
$$\times \prod_{k > k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \, \mathbf{z} \prod_{1 \le \ell \ne k^0 \le k} g_\ell + F_{K+1})\Big],$$

which, up to some normalising constant, is the same as (C.14) up to the following change of support

$$\mathbb{1}_{g \in (0,1)^K} \longleftrightarrow \mathbb{1}_{g' \in (0,1)^{k^0-1} \times (0,\tau) \times (0,1)^{K-k^0-1}}.$$

By an abuse of notation, we denote by $\mathbf{p}$ this function, namely

$$\mathbf{p}(g) = \prod_{k < k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \prod_{\ell=1}^{k} g_\ell + F_{K+1})\Big]$$
$$\times \prod_{k > k^0} g_k^{K-k} \cosh\Big[\mu_{\bar{\iota}_k}^0 ((1 - F_{K+1}) \, \mathbf{z} \prod_{1 \le \ell \ne k^0 \le k} g_\ell + F_{K+1})\Big].$$
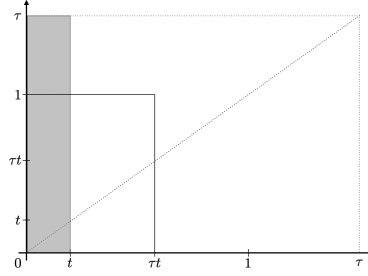

57

Figure 10: The two boxed rectangles have Lebesgue measure, namely τt. The $\mathbf{p} \otimes \mathbf{p}$ measure of the grey box is greater than the $\mathbf{p} \otimes \mathbf{p}$ measure of the white box.

We deduce that

$$
\begin{aligned}
\mathbb{F}_{z_{k^0}}^{(k^0+1)}(t) \geq \mathbb{F}_{z'_{k^0}}^{(k^0+1)}(t) \quad &\Leftrightarrow \quad \overline{\mathbb{P}}(G_{k^0+1} \leq t | G_{k^0} = z_{k^0}) \geq \overline{\mathbb{P}}(G_{k^0+1} \leq t | G_{k^0} = z'_{k^0}) \\
&\Leftrightarrow \quad \overline{\mathbb{P}}(G_{k^0+1} \leq t | G_{k^0} = z_{k^0}) \geq \overline{\mathbb{P}}(G'_{k^0+1} \leq \tau t | G_{k^0} = \tau z_{k^0}) \\
&\Leftrightarrow \quad \frac{\int_{\mathscr{D}(t)} \mathbf{p}}{\int_{\mathscr{D}(1)} \mathbf{p}} \geq \frac{\int_{\mathscr{D}(\tau t)} \mathbf{p}}{\int_{\mathscr{D}(\tau)} \mathbf{p}} \\
&\Leftrightarrow \quad \int_{\mathscr{D}(t) \times \mathscr{D}(\tau)} \mathbf{p} \otimes \mathbf{p} \geq \int_{\mathscr{D}(\tau t) \times \mathscr{D}(1)} \mathbf{p} \otimes \mathbf{p}, \quad\quad\quad \text{(C.15)}
\end{aligned}
$$

where

$$
\mathscr{D}(s) := \left\{ (g_1, \ldots, g_{k^0-1}, g_{k^0+1} \ldots, g_K) \in (0,1)^{K-1} \; : \; 0 < g_{k^0+1} \leq s \right\}.
$$

We now present an inequality on the to conclude. Observe that we are integrating on domains depicted in Figure 10. The two boxes have same area for the uniform measure and we would like to compare their respective measure for the $\mathbf{p} \otimes \mathbf{p}$ measure. We start by the next lemma whose proof is omitted.

Lemma 22. *Let $a, b \geq 0$. The function*

$$
z \mapsto \cosh(a z + b) \times \cosh(a/z + b)
$$

is non-decreasing on the domain $[1, \infty)$.

Now, let $(g_1, \ldots, g_{k^0-1}, g_{k^0+2} \ldots, g_K) \in (0,1)^{K-1}$ be fixed in the integrals (C.15). We are the looking at the weights of the domains $(h_1, h_2) \in (0, t) \times (0, \tau)$ and $(h_3, h_4) \in$

58

$(0, \tau t) \times (0,1)$ for the weight function w given by

$$w(h_1, h_2) = C_1 h_1^{K-k^0-1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell<k^0} g_\ell \times h_1 + F_{K+1})\right]$$

$$\times \prod_{k>k^0+1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell\ne k^0, k^0+1\le k} g_\ell \times h_1 + F_{K+1})\right]$$

$$\times h_2^{K-k^0-1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell<k^0} g_\ell \times h_2 + F_{K+1})\right]$$

$$\times \prod_{k>k^0+1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell\ne k^0, k^0+1\le k} g_\ell \times h_2 + F_{K+1})\right],$$

where the constant C_1 depends on $(g_1, \ldots, g_{k^0-1}, g_{k^0+2} \ldots, g_K) \in (0,1)^{K-1}$. By the change of variables $h_1' = h_3/t$ and $h_2' = th_4$, the right hand term of (C.15) is given by the integration on the domain $(h_1', h_2') \in (0,t) \times (0,\tau)$ of the weight function w' given by

$$w'(h_1', h_2') = C_1 h_1'^{K-k^0-1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell<k^0} g_\ell \times t \times h_1' + F_{K+1})\right]$$

$$\times \prod_{k>k^0+1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell\ne k^0, k^0+1\le k} g_\ell \times t \times h_1' + F_{K+1})\right]$$

$$\times h_2'^{K-k^0-1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell<k^0} g_\ell \times h_2'/t + F_{K+1})\right]$$

$$\times \prod_{k>k^0+1} \cosh\left[\mu_{\bar{\imath}_k}^0((1-F_{K+1})\, z_{k^0} \prod_{1\le\ell\ne k^0, k^0+1\le k} g_\ell \times h_2'/t + F_{K+1})\right].$$

Now, invoke Lemma 22 with

$$a = \mu_{\bar{\imath}_k}^0(1-F_{K+1})\, z_{k^0} \prod_{1\le\ell<k^0} g_\ell \times h$$

$$b = \mu_{\bar{\imath}_k}^0 F_{K+1}$$

$$z = t \ge 1,$$

where $h = h_1$ or h_2, to get that $w' \ge w$ and so

$$\int_{\mathscr{D}(t)\times\mathscr{D}(\tau)} \mathbf{p} \otimes \mathbf{p} \ge \int_{\mathscr{D}(\tau t)\times\mathscr{D}(1)} \mathbf{p} \otimes \mathbf{p},$$

which concludes this part of the proof.

○ *Step 3.3:* We continue by induction with the other transport maps in Knothe-Rosenblatt's construction. Assume that we have built $z' := (z_k', \ldots, z_{k^0}')$ and $z := (z_k, \ldots, z_{k^0})$ for some $k > k^0$. Denote $\mu_z^{(k+1)}$ the following conditional law

$$\mu_z^{(k+1)} := \text{law}\left[G_{k+1} | \{\bar{\imath}_1, \ldots, \bar{\imath}_K, F_{K+1}, \underbrace{G_k = z_k, \ldots, G_{k^0} = z_{k^0}}_{\text{denoted } G^{[k,k^0]}=z}\}\right],$$

59

and $\mathbb{F}_z^{(k+1)}$ its cdf. Denote $\mu_{z'}^{(k+1)}$ the following conditional law

$$\mu_{z'}^{(k+1)} := \mathrm{law}\Big[G_{k+1}|\{\bar{\imath}_1,\ldots,\bar{\imath}_K, F_{K+1}, \underbrace{G_k = z_k',\ldots,G_{k^0}=z_{k^0}'}_{G^{[k,k^0]}=z'}\}\Big],$$

and $\mathbb{F}_{z'}^{(k+1)}$ its cdf. Note that $z \leq z' = T^{(k)}(z) \leq 1$. Again, we would prove that $\mathbb{F}_z^{(k+1)} \geq \mathbb{F}_{z'}^{(k+1)}$ which implies that the transport map $T^{(k+1)} := \left(\mathbb{F}_{z'}^{(k+1)}\right)^{-1} \circ \mathbb{F}_z^{(k+1)}$ satisfies $T^{(k+1)}(u) \geq u$ for all $u \in (0,1)$.

For $\mathbf{z} \in (0,1)^{k-k^0} \times (x,1)$, the conditional density of $G|\{\bar{\imath}_1,\ldots,\bar{\imath}_K, F_{K+1}, G^{[k,k^0]} = \mathbf{z}\}$ is

$$(\mathrm{const})\, \mathbb{1}_{g\in(0,1)^K} \mathbb{1}_{g^{[k,k^0]}=\mathbf{z}} \prod_{m<k^0} g_m^{K-m} \cosh\Big[\mu_{\bar{\imath}_m}^0\big((1-F_{K+1})\prod_{\ell=1}^m g_\ell + F_{K+1}\big)\Big]$$

$$\times \prod_{k^0\leq m\leq k} \mathbf{z}_m^{K-m} \cosh\Big[\mu_{\bar{\imath}_m}^0\big((1-F_{K+1})\prod_{1\leq\ell<k^0} g_\ell \prod_{n=k^0}^m \mathbf{z}_n + F_{K+1}\big)\Big]$$

$$\times \prod_{k<m} g_m^{K-m} \cosh\Big[\mu_{\bar{\imath}_m}^0\big((1-F_{K+1}) \prod_{1\leq\ell<k^0} g_\ell \prod_{n=k^0}^k \mathbf{z}_n \prod_{k<\ell\leq m} g_\ell + F_{K+1}\big)\Big].$$

Set $\tau := \prod_{n=k^0}^k z_n' / \prod_{n=k^0}^k z_n \geq 1$ and $G_k' = \tau G_{k^0+1}$ so that

$$\Big[\prod_{n=k^0}^k z_n'\Big]G_{k+1} = \Big[\prod_{n=k^0}^k z_n\Big]G_{k+1}'.$$

Then the proof follows the same idea as in *Step 3.2* and we will not detail it here.

∘ *Step 3.4:* This is the last step of the proof. Assume that we have built $z' := (z_K',\ldots,z_{k^0}')$ and $z := (z_K,\ldots,z_{k^0})$. Denote $\mu_z^{(k^0-1)}$ the following conditional law

$$\mu_z^{(k^0-1)} := \mathrm{law}\Big[G_{k^0-1}|\{\bar{\imath}_1,\ldots,\bar{\imath}_K, F_{K+1}, G^{[K,k^0]} = z\}\Big],$$

and $\mathbb{F}_z^{(k^0-1)}$ its cdf. Denote $\mu_{z'}^{(k^0-1)}$ the following conditional law

$$\mu_{z'}^{(k^0-1)} := \mathrm{law}\Big[G_{k^0-1}|\{\bar{\imath}_1,\ldots,\bar{\imath}_K, F_{K+1}, G^{[K,k^0]} = z'\}\Big],$$

and $\mathbb{F}_{z'}^{(k^01)}$ its cdf. Note that $z \leq z' = T^{(K)}(z) \leq 1$. Again, we would prove that $\mathbb{F}_z^{(k^0-1)} \geq \mathbb{F}_{z'}^{(k^0-1)}$ which implies that the transport map $T^{(k^0-1)} := \left(\mathbb{F}_{z'}^{(k^0-1)}\right)^{-1} \circ \mathbb{F}_z^{(k^0-1)}$ satisfies $T^{(k^0-1)}(u) \geq u$ for all $u \in (0,1)$.

For $\mathbf{z} \in (0,1)^{K-k^0} \times (x,1)$, the conditional density of $G|\{\bar{\imath}_1,\ldots,\bar{\imath}_K, F_{K+1}, G^{[K,k^0]} = \mathbf{z}\}$ is

$$(\mathrm{const})\, \mathbb{1}_{g\in(0,1)^K} \mathbb{1}_{g^{[K,k^0]}=\mathbf{z}} \prod_{m<k^0} g_m^{K-m} \cosh\Big[\mu_{\bar{\imath}_m}^0\big((1-F_{K+1})\prod_{\ell=1}^m g_\ell + F_{K+1}\big)\Big]$$

$$\times \prod_{k^0\leq m\leq K} \mathbf{z}_m^{K-m} \cosh\Big[\mu_{\bar{\imath}_m}^0\big((1-F_{K+1}) \prod_{1\leq\ell<k^0} g_\ell \prod_{n=k^0}^m \mathbf{z}_n + F_{K+1}\big)\Big].$$

60

Now, let $(g_1, \ldots, g_{k^0-2}) \in (0,1)^{k^0-2}$ be fixed and denote by

$$\forall g \in (0,1), \quad w_z(g) := g^{K-k^0+1} \cosh\Big[\mu_{i_{k^0-1}}^0\big((1-F_{K+1})\prod_{\ell=1}^{k^0-2} g_\ell \times g + F_{K+1}\big)\Big]$$

$$\times \prod_{k^0 \leq m \leq K} \mathbf{z}_m^{K-m} \cosh\Big[\mu_{i_m}^0\big((1-F_{K+1})\prod_{n=k^0}^{m} \mathbf{z}_n \prod_{\ell=1}^{k^0-2} g_\ell \times g + F_{K+1}\big)\Big].$$

and, substituting z by z', define $w_{z'}$ as well. Let $t \in (0,1)$. Following the idea of *Step 3.2*, one can check that it is sufficient to prove that

$$\int_0^t \Big(\int_0^1 w_z(g) w_{z'}(g') dg'\Big) dg \geq \int_0^1 \Big(\int_0^t w_z(g) w_{z'}(g') dg'\Big) dg.$$

Substituting

$$\int_0^t \Big(\int_0^t w_z(g) w_{z'}(g') dg'\Big) dg$$

on both parts, one is reduced to prove that

$$\int_0^t \Big(\int_t^1 w_z(g) w_{z'}(g') dg'\Big) dg \geq \int_0^t \Big(\int_t^1 w_{z'}(g) w_z(g') dg'\Big) dg.$$

Observe that $g \leq g'$ in the last two integrals. Now, we have this lemma whose proof is omitted.

Lemma 23. *Let $0 < a \leq a'$ and $b > 0$. The function*

$$z \mapsto \frac{\cosh(az+b)}{\cosh(a'z+b)}$$

is non-increasing on the domain $(0, \infty)$.

Let $g \leq g'$. From Lemma 23, we deduce that $\cosh(ag+b)\cosh(a'g'+b) \geq \cosh(ag'+b)\cosh(a'g+b)$, proving that $w_z(g)w_{z'}(g') \geq w_{z'}(g)w_z(g')$. It proves that $T^{(k^0-1)}(u) \geq u$ for all $u \in (0,1)$.

We then proceed by induction for $k^0 - 1 \to k^0 - 2 \to \cdots \to 1$. The proof follows the same line as above, *Step 3.4*.

Appendix D: A Quasi Monte Carlo (QMC) method: Cubature by lattice rule

Our goal is to compute the integral of some function f on the hypercube of dimension d, namely

$$I := \int_{[0,1]^d} f(x) dx.$$

We want to approximate it by a finite sum over n points

$$I_n := \frac{1}{n} \sum_{i=1}^{n} f(x^{(i)}).$$

61

A convenient way of constructing the sequence $x^{(i)}, i = 1, \dots, n$ is the so-called *lattice rule*: from the first point $x^{(1)}$ we deduce the others $x^{(i)}$ by

$$x^{(i)} = \left\{ i.x^{(1)} \right\},$$

where the {} brackets mean that we take the fractional part coordinate by coordinate. In such a case the error given by

$$E(f, n, x^{(1)}) = I - I_n$$

is a function, in particular, of starting point $x^{(1)}$.

The Fast-rank algorithm (Nuyens and Cools, 2006) is a fast algorithm that finds, component by component and as a function of the prime n, the sequence of coordinates of $x^{(1)}$ that minimizes the maximal error when f varies in a unit ball $\mathscr{E}$ of some *RKHS*, namely a tensorial product of *Koborov spaces*. In addition it gives an expression of its minimax error, namely

$$\max_{f \in \mathscr{E}} (f, n, x^{(1)}).$$

In practice, very few properties are known on the function f, so the result above is not directly applicable. Nevertheless for many functions f, it happens that the convergence of I_n to I is "*fast*": typically of the order $1/n$ while the Monte-Carlo method (choosing the $x^{(i)}$ *at random*) converges at rate $1/\sqrt{n}$.

A reliable estimate of the error is obtained by adding a *Monte-Carlo layer* as in Genz (1992) for instance. This can be done as follows. Let U a **unique** uniform variable on $[0,1]^d$, we define

$$x_U^{(i)} := \left\{ i.x^{(1)} + U \right\}, \quad I_{n,U} := \frac{1}{n} \sum_{i=1}^{n} f(x_U^{(i)}).$$

Classical computations show that $I_{n,U}$ is now an unbiased estimator of I. In a final step, we perform N (in practice 15-20) independent repetitions of the experiment above an we compute usual asymptotic confidence intervals for independent observations.
